Introduction

Tamabo [*tama^{m}bo*] (Malo) is the predominant dialect of the language of the island of Malo (previously known as St. Bartholomew) in northern Vanuatu, in the southwest Pacific (**Figure 1**). It is spoken by at least 3000 people including those living on Malo, and those who have settled on the nearby 'big' island of Espiritu Santo and in Port Vila. It is learned as a first language by most children on the island, although Bislama (Vanuatu pidgin) is strengthening in almost all social contexts. Tamabo was originally the dialect of the western side of Malo; the dialect of the east [*tamapo*] is now used by no more than a handful of older speakers, although some words from that dialect are heard in several old dance songs. There is no written literature in the language, except for some copies of Presbyterian mission publications dating from the 1890s. Nevertheless, a strong oral tradition of storytelling has been maintained, and activities reflecting *Kastom* (traditional custom) such as dances, and 'fighting sticks' contests [*ma^{n}ja*] are enjoying renewed interest and participation.

Grammatical Overview

The language is Oceanic (Austronesian); it belongs to the Northern Vanuatu linkage, and appears similar to languages of nearby Tangoa, Araki, and south Santo. Tamabo can be regarded as conservative in that it shares many of the same structural characteristics widely distributed among Oceanic languages, and many of which are posited for Proto-Oceanic (POc).

Tamabo is a nominative-accusative language, and the unmarked word order of the clause is Agent-Verb-Object or Subject-Verb. Sentence types other than the declarative are based on the unmarked declarative form. Basic clauses are most commonly verbal clauses that indicate a non-future/future contrast. There are also verbless clauses where the predicate is a noun phrase, a numeral, or a prepositional phrase. Basic noun phrase structure is similar to that outlined for POc (Lynch *et al.*, 2002: 75) with the noun as head, preceded by an article (retained only in some syntactic environments in Tamabo), and an optional premodifier such as a quantifier, and followed by an optional modifier or demonstrative. It is an agglutinating language with considerable derivational morphology and valency-changing affixes.

Lexically, many words in the language are reflexes of words posited for POc. Other characteristics common to many Oceanic languages are reflected in

Introduction

Tamabo [*tama^{m}bo*] (Malo) is the predominant dialect of the language of the island of Malo (previously known as St. Bartholomew) in northern Vanuatu, in the southwest Pacific (**Figure 1**). It is spoken by at least 3000 people including those living on Malo, and those who have settled on the nearby 'big' island of Espiritu Santo and in Port Vila. It is learned as a first language by most children on the island, although Bislama (Vanuatu pidgin) is strengthening in almost all social contexts. Tamabo was originally the dialect of the western side of Malo; the dialect of the east [*tamapo*] is now used by no more than a handful of older speakers, although some words from that dialect are heard in several old dance songs. There is no written literature in the language, except for some copies of Presbyterian mission publications dating from the 1890s. Nevertheless, a strong oral tradition of storytelling has been maintained, and activities reflecting *Kastom* (traditional custom) such as dances, and 'fighting sticks' contests [*ma^{n}ja*] are enjoying renewed interest and participation.

Grammatical Overview

The language is Oceanic (Austronesian); it belongs to the Northern Vanuatu linkage, and appears similar to languages of nearby Tangoa, Araki, and south Santo. Tamabo can be regarded as conservative in that it shares many of the same structural characteristics widely distributed among Oceanic languages, and many of which are posited for Proto-Oceanic (POc).

Tamabo is a nominative-accusative language, and the unmarked word order of the clause is Agent-Verb-Object or Subject-Verb. Sentence types other than the declarative are based on the unmarked declarative form. Basic clauses are most commonly verbal clauses that indicate a non-future/future contrast. There are also verbless clauses where the predicate is a noun phrase, a numeral, or a prepositional phrase. Basic noun phrase structure is similar to that outlined for POc (Lynch *et al.*, 2002: 75) with the noun as head, preceded by an article (retained only in some syntactic environments in Tamabo), and an optional premodifier such as a quantifier, and followed by an optional modifier or demonstrative. It is an agglutinating language with considerable derivational morphology and valency-changing affixes.

Lexically, many words in the language are reflexes of words posited for POc. Other characteristics common to many Oceanic languages are reflected in

Figure 1 Malo Island within Vanuatu.

Tamabo: they include a subject proclitic on the verb root, marking of inclusive and exclusive distinctions in pronouns, spatial concepts 'seaward' vs. 'inland,' 'up direction' vs. 'down direction' (depending on location on island) indicated by particular verbs and/or location nouns, possessive constructions with noun phrases reflecting the semantics of alienable and inalienable possession, and 'tail-head' linkage of clauses in procedural narrative.

Phonology

Tamabo reflects many of the consonants of the reconstructed POc paradigm (Lynch *et al.*, 2002: 63) with little or no phonetic change. Voiced stops are prenasalized.

Bilabial		Dental-alveolar		Pre-palatal	Velar	
b	b^w	t	d	ɟ	k	
m	m^w		n			ŋ
β	$β^w$		s		x	
			r			
			l			

Like POc, there is a five-vowel system, sequences of unlike vowels are permitted, and syllable structure is primarily (C)V.

Orthography

The four prenasalized stops are written as b, bw, d, j. Fricative /β/ is written as v, the additionally labialized fricative as w; /x/ is represented by h, /m^w/ by mw and /ŋ/ as ng.

Examples of Particular Grammatical Characteristics

Productive Derivations from Affixation, Reduplication, and Compounding

Affixes to nouns

-ha *noun-like quality*	dodo → dodo-ha	'night' → 'be cloudy/dark'
-a *nominalization*	luhu → luhu-a	'hide'→ 'refuge'
vo- *female*	natuku → vo-natuku	'my child/son' → 'my daughter'
ta- *person belonging to*	ta-Alotu 'Santo person'	
vu- *tree*	vu-talaua 'sago palm tree'	
lo- *plural (trees only)*	lo-vu-talaua 'sago palm trees'	
ra- *female plural/leaf*	ra-vavine 'women'; ra-talaua 'sago palm leaf'	

Reduplication of nouns and verbs

hinau → hina-hinau	'thing' → things
mata → mata-mata	'eye' → 'signs'
bange → bange-bange	'stomach' → 'pregnant'
mana → mana-mana	'laugh' → 'friendly'
sahe → sahe-sahe	'go up' → 'keep going up'
tau → tau-tau	'put s.t in place' → 'put many things in place'

Compounding (noun + noun; noun + verb; verb + verb)

mara-rohai 'man-leaf/leaves'	→ 'medicine man'
mata-suri 'eye-follow'	→ 'be jealous'
bosi-mate 'turn-die'	→ 'extinguish (lamp)'

Valency Changing Affixes

-hi, -si 'applicatives'; ma- 'agentless passive'; va-/vaha- 'causative', and vari- 'anti-passive'

sora → sora-hi	'talk' → 'talk about s.t.'
lua → lua-si	'vomit' → 'vomit on s.t.'
duru → ma-daru	'split s.t.' → 'be split'
mauru → vaha-mauru	'be alive'→ 'save life'
hati → vari-hati	'bite s.t.' → 'inclined to bite'

Serial Verb Constructions for a Variety of Functions

Action in specified direction

vavine	le-hilo	le-sahe
woman	*ASP-look*	*ASP-go.up*
ta-vonavu	mo-dono	mo-jivo
belong-Malakula	*3.sing-sink*	*3.sing-go.down*
ana	tarusa	
PREP	*sea*	

'while the woman was looking up, the Malakula man drowned in the sea'

Comparative

heletu	niani	mo-suiha
pig	*this*	*3.sing-strong*
mo-liu-ra		
3.sing-win.over-O.3PL		

'this pig is the strongest of them'

Continuative aspect

ku-vano	ku-le	ovi,	ku-ovi
1.sing-go	*1.sing-ASP*	*stay*	*1.sing-stay*
mo-vano	mo-vano . . .		
3.sing-go	*3.sing-go*		

'I went and I was waiting, I kept on and on waiting . . .'

Completive aspect

voi	mo-mule	mo-iso
mum	*3.sing-head.home*	*3.sing-finish*

'mum has already gone home'

Non-result

ka-te	soari-a,	ka-sai-a
1PL-NEG	*see-OBJ.3.sing*	*1PL-search-OBJ.3 sing*
mo-tete		
3.sing-negative		

'we didn't see it, we searched for it to no avail'

Possessive Constructions

Classifiers for inalienable possession

no-	personal property	
	no-da vanua	'our (INCL) house'
ma-	drinkable	
	ma-m reu	'your (sing.)water (to drink)'

ha- edible
ha-mam vetai 'our (EXCL) bananas'
bula- living things (animals, crops + things regarded as 'living')
bula-ra toa 'their chickens'; bula-ku redio 'my radio'

Overlap between constructions or classifiers
no-ku nunu 'my photo' (that I own)
nunu-ku 'my photo' (of me)
bula-na dam 'his yam/s' (growing)
ha-na dam 'his yam/s' (to eat)

Hierarchy of Individuation: Kin Terms/Proper Names→ Animate→ Inanimate

Differentiation of kin/proper names vs. common nouns
— *comitatives* mai/mana
Voi mai Alis vavine atea mana mwera atea
'Mum and Alice' 'a girl and a boy'

— *possessive linkers* ni/i *indicating 'status' of possessor*
naho-ni mama vuti-ni Abae tamanatu-i vavine ridi
face-POSS dad *hill/s-POSS Ambae.* *husband-POSS woman DEF*
'dad's face' 'the hills of Ambae' 'the woman's husband'

— *prepositions* hini/ hina
hini Air Vanuatu hina siba
'with Air Vanuatu' 'with a knife'

Differentiation of animate vs. inanimate
— *quantitative verbs*
tamalohi na-were heletu na-were sala mo-were
person 3PL-be.many *pig 3PL-be.many* *road 3sing-be.many*
'many people' 'many pigs' 'many roads'

— *prepositions* telei/ana
telei-au telei bula-ku vuria ana tano
'to me' 'to my dog' 'to the garden'

Tamil

H F Schiffman, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Tamil is the Dravidian language with the most ancient literary tradition in India, dating from the early centuries A.D. or before. The earliest (3rd–1st century B.C.) inscriptions of Tamil are found in caves used by Buddhist and Jain monks, in a form known as Tamil *Brahmi* script. The earliest text in Tamil is a grammar, the *Tolkaappiyam*, which describes *centamiṟ* (Old Tamil) with both literary and colloquial (*koDuntamiṟ*) dialects, spoken in what is now Tamilnadu and Kerala, in South India. An early and original poetic literature, known as *Sangam* Tamil, has survived in the form of various anthologies; these early texts show few borrowings from Sanskrit, and minimal Brahmanic or 'Hindu' influences. After Old Tamil, a Middle Tamil literature can be distinguished, marked by diverse influences, including increasing Aryanization, Buddhism, and Jainism. Two epics, the *Cilappatikaram* (The lay of the ankle bracelet) and *Manimekalai* (The girdle of jewels), a Buddhist work, date from the 4th–6th centuries A.D., and the *Tirukkural*, known to every Tamil and considered by many to be the apex of their literary genius. In the 6th–9th centuries, *bhakti* devotional poetry (the hymns of the Alvars and Nayanars), devotional literature honoring Vaishnava and Shaiva saints, developed, then spread as a phenomenon across India.

From this period until the arrival of Western colonizers and missionaries, Tamil literature reflects pan-Indian norms devoted to philosophical and religious writings, with little originality (and heavy Sanskritization) except for the poetry of Kampan. After the consolidation of colonialism, Tamil literature shows more influences of Western, especially English, ideas. But the development of English education in India also stimulated resistance to these norms and a

Tamil

H F Schiffman, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Tamil is the Dravidian language with the most ancient literary tradition in India, dating from the early centuries A.D. or before. The earliest (3rd–1st century B.C.) inscriptions of Tamil are found in caves used by Buddhist and Jain monks, in a form known as Tamil *Brahmi* script. The earliest text in Tamil is a grammar, the *Tolkaappiyam*, which describes *centamiṟ* (Old Tamil) with both literary and colloquial (*koDuntamiṟ*) dialects, spoken in what is now Tamilnadu and Kerala, in South India. An early and original poetic literature, known as *Sangam* Tamil, has survived in the form of various anthologies; these early texts show few borrowings from Sanskrit, and minimal Brahmanic or 'Hindu' influences. After Old Tamil, a Middle Tamil literature can be distinguished, marked by diverse influences, including increasing Aryanization, Buddhism, and Jainism. Two epics, the *Cilappatikaram* (The lay of the ankle bracelet) and *Manimekalai* (The girdle of jewels), a Buddhist work, date from the 4th–6th centuries A.D., and the *Tirukkural*, known to every Tamil and considered by many to be the apex of their literary genius. In the 6th–9th centuries, *bhakti* devotional poetry (the hymns of the Alvars and Nayanars), devotional literature honoring Vaishnava and Shaiva saints, developed, then spread as a phenomenon across India.

From this period until the arrival of Western colonizers and missionaries, Tamil literature reflects pan-Indian norms devoted to philosophical and religious writings, with little originality (and heavy Sanskritization) except for the poetry of Kampan. After the consolidation of colonialism, Tamil literature shows more influences of Western, especially English, ideas. But the development of English education in India also stimulated resistance to these norms and a

renaissance and revival of Tamil, focusing on purifying the language of Indo-Aryan and other loan words.

The Tamil language has had its current standard written form since the thirteenth century, when codified again in the grammar *nannuul*, composed (according to some accounts) by the Jaina monk Pavanandi. But due to increasing diglossia (Britto, 1986), spoken Tamil dialects have now diverged so radically from earlier norms, including the written standard (LT, or Literary Tamil; Arden, 1942) that no spoken dialect (regional or social) can function as the koiné or lingua franca. Since LT is never used for authentic informal oral communication between live speakers, there has always been a need for some sort of spoken 'standard' for inter-dialect communication, and what has evolved has been hastened by the development of modern communication, especially the 'social' film, which is the chief disseminator of this 'standard spoken Tamil' (SST). This form (Schiffman, 1999), based on the everyday speech of educated non-Brahman Tamils, is understood wherever Tamil is spoken, including Sri Lanka, Malaysia, and Singapore.

The sound system of Tamil consists of a ten-vowel system with long and short *i* and *iː*, *e* and *eː*, *a* and *aː*, *o* and *oː*, and *u* and *uː*. The diphthongs *ai* and *au* are found in LT but are not usual in ST; a few loan words contain *au*, but often these can be represented by *avu* as in *pavuŋɖu* 'pound.' The vowel *u* has an unrounded variant [ɯ] that occurs after the first syllable, and there are also nasalized variants [ã], [õ], as well as nasalized versions of [ẽ] and [ũ], all found in final position only (as the result of deletion of final nasals in SST, but not in LT).

In LT, as in Proto-Dravidian, there was a series of six stop consonants: velar *k*, palatal *c*, retroflex *ʈ*, alveolar *t̲*, dental *t*, and labial *p*. The apical stops *ʈ* and *t̲* could not occur in initial position. In non-initial position, all stops were voiced after nasals (i.e., they were phonetically *g, j, ɖ, d̲*, *d*, and *b*), and intervocalically, unless geminated, they were laxed (i.e., phonetically *h, s*, flapped *ɾ*, flapped *r*, *ð*, and *v*). Since these variants are in complementary distribution, no contrast between voiced and voiceless consonants (and the fricative variants) existed. In modern SST, because of borrowings, voiced consonants occur in other environments than these, so the phonological system now has voiced stops, though the orthography lacks provisions for this.

Today because of the loss of the alveolar contrast, modern SST only has contrasts between five points of articulation in consonantal stops, with voiced variants in many loan words (but also in onomatopoeic expressions, of which there are many). Nasal consonants (despite orthographic symbols for all six positions) are only *m*, *n*, and retroflex *ɳ*. In the area of laterals and rhotics, there is confusion. Proto-Dravidian surely had contrasts between *l* and retroflex *ɭ*, and *r* and *ɻ* a 'retroflex frictionless continuant' symbolized variously in transcriptions, but for which we prefer *ɹ*, but because of the loss of the intervocalic alveolar stop contrast (*t̲*), which is flapped [r] in modern speech, orthographic symbols for three r's exist. Furthermore, the retroflex continuant *ɹ*, which happens to be the final segment in the name 'Tamil' (*tamiɹ*) is often not maintained in speech in many dialects, merging instead with *ɭ*, *g*, and even *y*. But sociolinguistic pressure to maintain this sound, seen as quintessentially *Tamil*, results in much variation in its maintenance. As for glides, both *y* and *v* (which varies sometimes to [w]) are found.

Grammatically, Tamil can be characterized as 'agglutinative,' with long chains of easily-identifiable morphemes concatenated as suffixes. Noun morphology is fairly simple (there is no grammatical gender), and noun phrases require no agreement with adjectives and nouns. A seven-case system with a nonfinite set of postpositions recruited from lexical items both nominal and verbal, completes the picture. Example:

anta periya	*viiʈʈ-ukk-pakkattu-le-*	*rundu*
That large	house-DAT-near	LOC + ABL

'From the vicinity of that large house'

The verbal system is morphologically more complex, with various inflectional and derivational morphemes concatenated as suffixes. Example:

avarai	*eppaʈiyoo*	*anuppu-*	*vittu-viʈa-*	*veeŋʈum*
he-ACC	somehow	send	CAUS-COMPL-	MODAL

'Somehow or other, (we) have to get rid of him'

Syntactically, word order is SOV and left-branching. Grammaticalization processes have resulted in the incorporation of certain lexical verbs into the morphology of the verb as 'aspectual' markers, a phenomenon typical in many South Asian languages.

Speakers of Tamil – there are at present 60 million of them, mostly in South India – like to call their language the 'second classical language of India.' This implicit comparison with Sanskrit is based on the existence of a corpus of ancient texts, both literary and theoretical, the exact date of which is still very much controverted (see Wilden, 2002). The most ancient reliable sources of information on Tamil are the Tamil-Brāhmī inscriptions, some of which apparently date back to the third century B.C. (Mahadevan, 2003). As far as the corpus of texts is concerned, it is often said that its core was composed in the early centuries of this era, but there is no ancient written testimony, and we have to rely on indirect evidence. The literary part of the corpus consists mainly of two genres: love poems and war poems (see Ramanujan, 1985, for a sample). The theoretical part of the corpus is a collection of treatises, which seem to have a double function. They are, for a part of them, grammars of a language that can be called 'classical Tamil.' They are also tools for understanding a literature. The treatise considered to be the most ancient, the *Tolkāppiyam*, consists of three books, devoted respectively to *eḻuttu* ('letters'), *col* ('words'), and *poruḷ* ('[poetical] matters'). More recent treatises try to fit themselves in a fivefold scheme, where *poruḷ* has been further subdivided, with autonomous books being devoted to *yāppu* ('metrics') and *aṇi* ('ornaments'). What can be called 'grammar' in a restricted sense – and what would come closer to the Sanskrit *Vyākaraṇa* – is to be found in the two books on 'letters' and 'words,' and it has to be borne in mind that for many of their users they appeared as ancillary to an ultimate goal, which was the mastering of poetry (*ceyyuḷ*). Another important consideration is that the Tamil interest in language took place in a context of diglossia – as in many places in India – and that even when grammarians say that they have examined not only *ceyyuḷ* but also '[ordinary] usage' (*vaḻakku*), this does not necessarily mean a descriptive interest in real vernaculars. As far as the absolute chronology is concerned, the first book of *Tolkāppiyam* describes a writing system – making use of a dot (*puḷḷi*), for example, to distinguish between *ka* and *k* – that seems to fit with what epigraphists have found in the third stage of the "evolutionary development of the medial vowel notations" (Mahadevan, 2003: 231). This does not mean, however, that the whole book was composed at that time. The most probable hypothesis is that the *Tolkāppiyam* is a patchwork that reached its current form when a final compilation was made (see, for instance, discussions in Zvelebil, 1973).

A bare-bones description of the contents of *Tolkāppiyam* should mention at least that the most important topic in its first book is 'sandhi' (*puṇarcci*), which is what takes place at the juncture of two items, A and B. The various possibilities considered are, to mention the main cases, whether A and B are nouns *(peyar)* or verbs *(viṉai)*, whether the relationship between them has to do with case *(vēṟṟumai)* or not, whether A ends in a vowel *(uyir)*, in a consonant *(mey)*, or in an overshort *u (kuṟṟiyalukaram)*. The detailed analysis expands into hundreds of possibilities, because tentative general rules are often contradicted by exceptions for specific words (see Subrahmanya Sastri, 1930). As far as the second book is concerned, its main topic is a presentation of the two main and two secondary parts of speech: noun, verb, particle (*iṭaic col*, literally 'intermediate word'), and 'proper words' (*uric col*). An important parameter, common to noun and to verb, is the *tiṇai* ('class'), which can have two values and is further subdivided into five *pāl* ('genres'): masculine, feminine, and epicene plural (subdivisions of the *uyartiṇai* 'higher class'); plus neuter and neuter-plural (subdivisions of the *aḵriṇai* 'nonclass'). As presented by one rule, the most clear manifestation of the *pāl* of a noun is seen not in the noun itself but in the verb that accords with it (standing as its predicate).

In many respects, the *Tolkāppiyam* can only be apprehended now as the mythical origin that the Tamil grammatical tradition has chosen for itself, and which became fixed – in its text, if not in its interpretation – in the age of commentators, which starts, seen from our times, with Iḷampūraṇar, probably in the 12th century. That age was preceded by an age of lost treatises, such as that by Avinayaṉār, which is said to have almost eclipsed the *Tolkāppiyam* in its time (see Vijayavenugopal, 1968). This age also saw the advent of the *Vīracōḻiyam*, a Tamil grammar built on a Sanskrit model, which was not really followed. The age of commentators, considered to continue until the 18th century, was dominated by a (sometimes) implicit dialogue between the commentators of the *Tolkāppiyam* and those of *Naṉṉūl*, a 13th-century grammar that tried to be a synthesis of its predecessors. This dialogue took place in a South India where the religious landscape had changed several times, and this is probably the reason why some commentators wanted to view the supposedly unique author of the *Tolkāppiyam* as being himself the disciple of an even more mythical grammarian,

the vedic rishi Akattiyar (Agastya) (see Chevillard, 2000a). That age of commentators was followed by the age of editors, in the 19th and 20th centuries.

One of the most prominent sociolinguists and discourse analysts, Deborah Tannen has contributed immensely to the analysis of spoken discourse by examining aspects of conversational style, gender, frames, poetic features, narratives, and argument. Her primary focus has been on social interaction, and more recently on gender and family communication. Besides her academic success, Tannen has reached out to the general public, writing linguistic books and articles that have attracted media attention and have led to her appearance on American television, radio, and cable shows.

Tannen received an M.A. in English literature from Wayne State University in 1970. However, the 1973 Summer Linguistic Institute in Michigan was pivotal in her becoming a linguist. As Tannen said in an interview, the Institute's theme of Language and Context, and especially a course taught by Robin Lakoff, captured her heart and her imagination. Tannen was

the vedic rishi Akattiyar (Agastya) (see Chevillard, 2000a). That age of commentators was followed by the age of editors, in the 19th and 20th centuries.

One of the most prominent sociolinguists and discourse analysts, Deborah Tannen has contributed immensely to the analysis of spoken discourse by examining aspects of conversational style, gender, frames, poetic features, narratives, and argument. Her primary focus has been on social interaction, and more recently on gender and family communication. Besides her academic success, Tannen has reached out to the general public, writing linguistic books and articles that have attracted media attention and have led to her appearance on American television, radio, and cable shows.

Tannen received an M.A. in English literature from Wayne State University in 1970. However, the 1973 Summer Linguistic Institute in Michigan was pivotal in her becoming a linguist. As Tannen said in an interview, the Institute's theme of Language and Context, and especially a course taught by Robin Lakoff, captured her heart and her imagination. Tannen was

further inspired to earn her Ph.D. in linguistics under Lakoff at the University of California, Berkeley. Two other Berkeley professors played a fundamental role in her development: John Gumperz, and Wallace Chafe, while another influence was Erving Goffman. Work by Gumperz and his students, Maltz and Borker, on crosscultural communication, was the fundamental block on which Tannen built her theory of gender interaction as crosscultural communication, published in her highly acclaimed book, *You just don't understand: women and men in conversation* (1990). Chafe and Goffman influenced her work on schemata, frames, and footing, theories on which she built and expanded in her publications (1993a, 1994a) that focus on social interaction. Upon her graduation in 1979, Deborah Tannen was hired at Georgetown University, where she is one of only four professors holding the distinguished rank of University Professor. In addition, she has been a fellow at the Center for Advanced Study in the Behavioral Sciences in Stanford, California, and the Institute for Advanced Study in Princeton, New Jersey.

Tannen has been a prolific scholar and has published 19 books and over 100 academic articles. Several of her books have received numerous prestigious awards and have become *New York Times* best sellers. She has received grants from the National Science Foundation, National Endowment of the Humanities, and more recently from the Sloan Foundation for a project that examines conflict and parental identities at work and at home of middle-class, dual-career couples. In addition, she is the associate editor of *Language in Society* and serves on the editorial boards of many other linguistics journals.

In addition to her immense linguistic contributions, Tannen has published poetry, short stories, and personal essays. She has also written two plays: 'Sisters' and 'An Act of Devotion,' which was included in *The best American short plays: 1993–1994*.

Tannen exemplifies the linguist who feels that academic knowledge is not and should not be the privilege of the few. In 2005, she received the prestigious Linguistic Society of America award for 'Linguistics, language, and the public.' She has popularized many aspects of sociolinguistics and has raised the public's awareness of the importance of linguistics in personal relationships and the workplace.

Tanzania: Language Situation

A Kipacha, Open University of Tanzania, Tanzania

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The United Republic of Tanzania (formally the United Republic of Tanganyika and Zanzibar), covering 945 087 sq. km, is situated in southeastern Africa. It borders Uganda and Kenya on the north, including the shores of Lake Victoria. On the east, it has about 1000 km of coastline plus the offshore Indian Ocean islands of Pemba, Zanzibar, Mafia, and Kilwa (once a city-state). On the south, it borders Mozambique, Malawi, and Zambia. The River Ruvuma defines the border with Mozambique. Tanzania also shares Lake Malawi with Malawi and Mozambique on the south. On the west, Tanzania borders the Democratic Republic of Congo (separated by Lake Tanganyika), Rwanda, and Burundi.

Tanzania's population was estimated to be around 36 million as of July 2001. Only 23 percent of the population lives in urban areas, with a moderate increase in the urban population from 18 to 23 percent in 2002 (2002 Population and Housing Census). This ranks Tanzania as one of the least urbanized countries in sub-Saharan Africa. These statistics have an effect on language use and language shift in Tanzania.

Tanzania is a multiethnic and multilingual country. It is the only African country where speakers of the four Greenbergian phyla for African language classification converge demographically. The distinctive language families spoken in Tanzania are Niger-Congo (Bantu), Nilo-Saharan (Nilotic), Khoisan, and Afroasiatic (Cushitic). Ethnographically, SIL (2004) has identified 137 primary languages for Tanzania. Of those, 135 are living and 2 are extinct. Nonindigenous languages that are also active in Tanzania include English (which serves as the coofficial language), Asian languages (primarily Arabic, Persian, Hindu, Urdu, and Gujarati), Somali, and French.

History of Language Development in Tanzania

The language situation in Tanzania today has been shaped by four principal sources: (1) the Swahili language – a standard form based on the Unguja dialect and now a lingual franca and official language of Kenya and Tanzania; (2) the English language as introduced by the British colonial administration and missionaries after World War I and consolidated in the following domains: administration, civil service, legislation, higher education, the judicial system, the media, and international trade and diplomacy; (3) the indigenous African languages, comprising Bantu, Cushitic, Khoisan, and Nilotic languages; and (4) nonindigenous languages used by immigrants, including Arab and Indian languages, Somali, and French.

Precolonial Era

There have been speakers of Khoisan 'click' languages (Hadza and Sandawe) in some part of central Tanzania since the 1st and 2nd centuries A.D. Archaeological evidence suggests that these early Khoisan people migrated gradually into the western part of southern Africa, where they have multiplied to their current levels (Ehret, 2000: 290). The Southern Cushitic languages of the Iraqw cluster and Ma'a are also believed to have arrived in Tanzania by the 1st millennium A.D. (Nurse and Hinnebusch, 1993: 21). The presence of Nilo-Saharan speaking peoples, represented by the Luo and Maasai around the eastern side of the Lake Victoria basin and in the vicinity of Mount Kilimanjaro are extensions of the Eastern Sudanic subbranch of the Nilo-Saharan phylum.

The Bantu languages as spoken in Tanzania today are linked to the Eastern Bantu branch of the Niger-Congo family. They were brought to Tanzania by the descendants of the proto-Bantu peoples who moved into Great Lakes region around the 3rd century B.C. and proceeded into present-day Uganda, Kenya, and Tanzania. Others went as far as Zambia and parts of southern Africa. Ehret (2000: 295) notes that Bantu expansion proceeded at the expense of Khoisan and Cushitic languages. This is an ongoing process, as recently observed in the case of Rangi (F.30 in Guthrie's 1967–71 classification of Bantu languages) swallowing the Cushitic language of Burunge (Stegen, 2003: 2). The outcome of these historical processes, though complex, paved the way for the current distribution of most of Tanzania's indigenous languages, including Swahili. The early Swahili-speaking area forms a nearly continuous belt along the coastal line from the Tanga to Mtwara regions together with the offshore islands in the Indian Ocean. As early as the 18th and 19th centuries Swahili spread inland along the caravan trade route as far as Tabora in western Tanzania and Ujiji on Lake Tanganyika. Its development into a lingua franca and ultimately the national language is covered in Whiteley (1969) and Nurse and Spear (1995).

Colonial Era

Like most other African countries, Tanzania was exposed to various foreign influences during the

colonial period. German colonial language policy encouraged the use of Swahili in commerce, the military, administration, and education. Swahili prospered during the German administration, receiving extensive attention from administrators, missionaries, and linguists seeking to study it and promote its use. English was rarely used until 1918, when parts of the country became part of the British mandate following World War I. The British influence and a nationalistic movement between 1919 and 1961 led to a bilingual English–Swahili language policy. English became the language of the schools and administration. During the 40 years of British rule Tanzania joined the anglophone camp in the international arena. Swahili enjoyed institutional and local support as a lingua franca and 'sub-official' language. The losers were the vernacular languages.

English and Swahili harmoniously divide between them key domains such as education, legislation, trade, the media, and national forums. Swahili is used in primary schools and the lower courts. English is preferred in higher education and administration. English overrides Swahili in its privileged status as the language of the Tanzanian elites. However, the power and influence of Swahili among the majority of Tanganyikan and Zanzibarian people has never been underestimated by nationalistic leaders. Swahili was idolized as a symbol of the 'African-ness' of the society (Blommaert, 1994) and this sensibility was carried over to postcolonial times. It was a driving force behind declaring Swahili a national and official language. Swahili became the language of the parliament and the mainstay of language policy and planning in independent Tanzania.

Postcolonial Era

The state of Swahili in the postindependence era is a success story that comes at the expense of both the ethnic community languages and English. However, it has been observed that powerful Swahili has failed to obliterate vernacular languages, but managed to limit them to mere 'home' and secluded domains such as culture identities, i.e., in rituals and folklore (Mekacha, 1993).

English and Swahili remain the country's undisputed formal languages, with the latter assuming the additional role of a lingua franca across Tanzania and between neighboring ethnic communities. The educational domain has become a battleground in the demarcation of roles between English and Swahili, and the perennial debate over whether to use English or Swahili in postprimary education is still active. No consensus has been reached between government authorities (who once exerted much effort to 'nationalize' Swahili) and pro-Swahili activists. Pro-English factions see the language as a doorway to the world's knowledge and economy. Others want to see Swahili replace English as a medium of instruction and thus forge a path towards a monolingual society and presumably solve the proficiency crisis (Yahya-Othman, 1990). Current economic and cultural realities seem to leave the Tanzanian people no choice but to become effectively multilingual. Effective language policy must be flexible enough to accommodate both internal and external economic and culture changes.

Other Foreign Languages in Tanzania

French-speaking immigrants from the Democratic Republic of Congo, Burundi, and Rwanda and the influx of asylum seekers and musicians from these countries contribute to a growing number of first-language speakers of French in Tanzania. Some are employed to teach French in private schools. There are also numerous French teachers at Dar es Salaam University and teacher training colleges. Alliance Française and the British Council are two culture centers geared to promoting and maintaining French and English language and culture in Tanzania. Although Germany ruled Tanzania in the early colonial period, German has had no impact on language use in modern Tanzania. However, there are a few scholars who graduated from German universities that have a working knowledge of German.

Linguistic Profile of the Indigenous Languages in Tanzania

All four phyla of African languages have been identified in Tanzania. The following is the distribution of each phylum with emphasis on the primary languages or language clusters. We will examine these phyla through the following branches: Cushitic, Khoisan, Southern Nilotic, and Bantu.

Cushitic

The Afroasiatic family is represented in Tanzania by the Cushitic subfamily. Tanzania is the only sub-Saharan country where speakers of the Southern Cushitic languages are present. Around four languages of the Iraqw cluster, with fewer than 1 million speakers, have been documented so far (see Hayward, 2000).

Khoisan

The smallest of the phyla in terms of distribution and population is the Khoisan group. The ancient Hadza (with about 400 current speakers) and Sandawe (about 10 000 speakers) in central Tanzania

are isolated cases of the Khoisan phylum outside the present main Khoisan-speaking territory of southwestern Africa.

Southern Nilotic

The Southern Nilotic branch of the Nilo-Saharan languages extends from Kenya down to northern Tanzania. A total of four main languages, Luo, Maasai, Datooga, and Ndorobo (Aramanik), with almost a million speakers, make up this branch. It occupies an area between the east of Lake Victoria bordering Kenya and northern Tanzania at the foot of Mount Kilimanjaro.

Bantu

The Bantu branch of the Niger-Congo language family has the largest group of speakers (95% of Tanzanians speak a Bantu language) and greatest number of languages (over 120 in Tanzania). It occupies a vast area, covering roughly three-quarters of Tanzania and its off-shore islands in the Indian Ocean. The major groups of Bantu languages as spoken in Tanzania (and elsewhere) are illustrated in Maho (2003) and more specifically in Nurse and Hinnebusch (1993).

Chaga/Taita Clusters (E60) Chaga (Chagga) is spoken on and in the vicinity of Mount Kilimanjaro in Tanzania.

West Tanzania Languages (Zone F) This group comprises Sukuma, Nyamwezi, Sumbwa, Kimbu, and Bungu. These are spoken in western Tanzania.

Rufiji-Ruvuma Languages (Zone P 10) This group includes Ndengereko, Ruihi (Rufiji), Matumbi, and Ngindo;
(P20) Yao, Mwera, Malone, Ndonde and Mabiha, Ndendeule;
(N10) Ngoni, Matengo, Mpoto, and Tonga.
It is spoken across southern Tanzania from the Indian Ocean to Lake Malawi.

Lacustrine (Western Highlands) (D60) Ruanda, Hangaza, Rundi, Ha, Subi (Shubi), Rutara, Haya, Dzindza, and Kerewe Suguti;
(E25) Jita, Kayak, and Rudi: Libya East Nana;
(E40) Curia, Zahakis, and Natal.
This group is spoken around Lake Victoria.

Lake Corridor (M10) Pimple, Runway, Fiat, Rung and Mamboed;
(M20) Wanda, Mange, Nihau, Mallet Safeway, Iwa, and Tambo;
(M30) Nyakyusa or Konde [Nyakyusa-Ngonde], etc.).
These are spoken in southwestern Tanzania and into Zambia and Malawi.

Swahili Dialects of Tanzania

Swahili in Tanzania consists of seven geographically based dialects (including Unguja, which has been formalized and designated as the standard dialect in Tanzania and Kenya):

- Standard Swahili/Unguja (G42)
- Pemba (G43a)
- Mafia/Mgao (G43d)
- Kae (G43c)
- Mtangata (G42c)
- Vumba (G42h)
- Tumbatu (G43b).

State of the Art

Market forces have obliged many Tanzanians to master basic communication skills in English to work in even junior positions in tourism, finance, and business. The continued teaching of English (whether formally or informally) consolidates and provides a positive environment for much-sought links with development agencies and donors, investors, and tourists, and provides a common language for the international exchange of technologies, conferences, trade, and international forums.

The relationship between Swahili and English is often asserted to be one of conflict rather than complement (Rubanza, 1995: 81). Some language activists have been lobbing to make Swahili mandatory at all levels of education. The conflict between a 'patriotic' allegiance to Swahili and the pragmatic and realistic demands of market forces has compelled decision makers to be hesitant about supporting pro-Swahili activists' demands. Public opinion in Tanzania agrees. There is a hardening of feeling against the use of Swahili as a medium of education even in primary schools. The Tanzanian government has recently allowed English-language primary schools to operate, and their popularity reflects the desire of the general public to remedy the low English-proficiency level in Tanzania.

There is a danger that allowing English proficiency to drop at the expense of Swahili will divide the nation into a privileged minority who are qualified to work in the world market and a majority who will be left to find work within localized public domains. The current low level of English competence at post-primary levels in Tanzania is largely the fault of a teaching methodology that does not emphasize communication skills (see Kipacha, 1993). Advocates of

English feel that there is no harm in Tanzanians mastering more than one or two languages when this can allow them to expand their horizons and open the door to the world. And in fact multilingualism and multiethnicity are the norm for the majority of Tanzanians today.

Conclusion

Tanzania is a Swahili-speaking society, at least in the public domain. English enjoys a privileged status as the language of international contact, international academia, and diplomatic discourse. Studies show that speakers of ethnic languages are declining but still surviving. The present challenge for Tanzania is how to achieve a mastery of English and Swahili on the one hand and preserve ethnic 'heritage' languages on the other. This paradox will continue to engage Tanzanian nationalists, language activists, and the public at large.

Tariana

A Y Aikhenvald, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Tariana language belongs to the Arawak language family (*see* **Arawak Languages**). It is spoken by about 100 people in the multilingual linguistic area of the Vaupés River Basin (northwest Amazonia, Brazil). This area is known (Aikhenvald, 2002b; Sorensen, 1967) for its multilingual exogamy: one can only marry someone who speaks a different language and belongs to a different tribe. People usually say: 'My brothers are those who share a language with me' and 'We don't marry our sisters.' The other languages in this area belong to the Tucanoan family, and they are still spoken by a fair number of people. The basic rule of language choice throughout the Vaupés area is that one should speak the interlocutor's own language. Descent is strictly patrilineal, and consequently, one identifies with one's father's language group. There is a strong cultural inhibition against 'language-mixing,' viewed in terms of lexical loans. In its grammatical and semantic structure, Tariana combines a number of features inherited from proto-Arawak, with the areal influences from Tucanoan in the form of grammatical calques and diffused patterns.

Tariana was once a dialect continuum spoken in various settlements along the Vaupés river and its tributaries. The Tariana clans used to form a strict hierarchy (according to their order of appearance as stated in the creation myth: see Aikhenvald, 1999). Lower-ranking groups in this hierarchy (referred to as 'younger siblings' by their higher-ranking tribes people) would perform various ritual duties for their 'elder siblings.' Each group spoke a different variety of the language. The difference between these varieties is comparable to that between Romance languages.

As the Catholic missions – and with them white influence – expanded, the groups near the top of the hierarchy abandoned the Tariana language in favor of the numerically dominant Tucano language. This process started in the early 1900s. The Tariana language is spoken nowadays just by people from two subtribes of the lowest-ranking group Wamiarikune, in two villages, Santa Rosa and Periquitos. The varieties are mutually intelligible. Most children are not learning Tariana any more. Innovative speakers of Tariana have more Tucanoan-like features in their language than traditional speakers. A literacy program in Tariana is presently under negotiation.

Tariana is a polysynthetic language, agglutinating with some fusion. It has mostly suffixes, with just a few prefixes. Constituent order depends on pragmatics. Younger speakers tend to put the verb last in the sentence, just like speakers of Tucano. There are mainly postpositions, with just one preposition (borrowed from Portuguese).

Tariana has 27 consonants (including a series of aspirated stops and pre-aspirated nasals and glide) and 15 vowels (*a, i, e, u*, each with a long and a nasal counterpart), *o* (with a nasal counterpart), and high central *ɨ*. Accent is distinctive and of pitch type, as a result of Tucanoan influence.

Underived adjectives form a closed class of about 30 members, while classes of nouns and verbs are open. Verbs divide into transitive and intransitive active, which take prefixes cross-referencing their subject (A/Sa). As is typical for an Arawak language, the same set of prefixes marks possessor on inalienably possessed nouns and the argument of postpositions. Intransitive stative verbs do not take any cross-referencing markers. Unlike any other Arawak language, grammatical relations in Tariana are also marked with cases: topical non-subject case *-nuku,* focused subject case *-ne/-nhe*, instrumental case *-ine*, and locative case *-se*. This case system for marking core syntactic functions was developed under the Tucanoan influence. The case markers result from the reanalysis of locative suffixes of Arawak origin. A member of any word class can occupy the intransitive predicate slot.

The locative and the instrumental cases can combine with the non-subject topical case if the constituent is topical (thus yielding a peculiar instance of 'double case').

Tariana has a complex system of more than 40 classifiers that are used as agreement markers on adjectives, as derivational affixes on nouns, and also as numeral and as verbal classifiers; a slightly different system of classifiers is used with demonstratives. A two-way gender opposition (feminine vs. the rest) is used in personal pronouns (third singular and all plural forms, thus contravening established universals) and in verbal cross-referencing. Classifiers are an open class, since any noun with an inanimate referent can be used as a 'repeater' (or 'self-classifier'). Repeaters can be used to mark the agreement with a topical noun while grammaticized classifiers are used for unmarked agreement.

There is an obligatory distinction between singular and plural for nouns with animate referent. Nouns with inanimate referent often refer to substances, and classifier suffixes are attached to them to specify

singular reference. For instance, *episi* means 'iron as a substance', while *episi-da* (iron-CLASSIFIER: ROUND) means 'axe' and *episi-kha* (iron-CLASSIFIER:CURVED) means 'wire'. Number agreement is optional for inanimate nouns.

The Tariana verb has a plethora of moods and aspects. It has an elaborate system of marking information source, known as evidentiality. Tariana distinguishes visual evidentials (something seen), non-visual evidentials (something heard, or smelled, or felt by touch), inferred evidential (something inferred based on visible results: as one infers that it has rained on the basis of puddles); assumed evidentials (based on general knowledge), and reported evidential. Three tenses (present, recent past, and remote past) are combined with evidentials. Traditional stories are typically cast in remote past reported evidential, and autobiographical narratives in visual evidential. Non-visual evidential is used to relate the actions of evil spirits that are not 'seen', and dreams of ordinary people, while prophetic dreams by omniscient shamans are cast in visual evidentials. A reduced set of evidentials is used in questions, while imperatives have just one, reported, evidential (meaning 'do something on someone else's order'). This unusually complex evidentiality system has been largely calqued from Tucanoan languages.

A complicated system of serial verb constructions expresses aspectual, directional, and sequential meanings, and also reciprocal and associative meanings. There are three types of causatives. Morphological causatives are formed on intransitive verbs. The same morpheme on a transitive verb indicates an advancement of a peripheral argument of the transitive verb to the core, and/or complete involvement and topicality of the O argument. Periphrastic causatives (indirect causation) and serial causative constructions (direct causation) are used to form causatives of transitive verbs.

When several clauses are combined to form one sentence, all but the main clause are marked differently depending on whether their subject is the same as, or different from, that of the main clause. This feature (known as switch-reference) is shared with the Tucanoan languages.

A detailed reference grammar is in Aikhenvald (2003). Aikhenvald (2002a) is a comprehensive dictionary, while Aikhenvald (1999) contains a text collection and an outline of the Tariana ethnography with an account of the kinship system (which is of Dravidian type).

Tarski, Alfred (1902–1983)

P P Chruszczewski, University of Wrocław, Wrocław, Poland

© 2006 Elsevier Ltd. All rights reserved.

Alfred Tarski (Teitelbaum) (1902–1983) was born on January 14, 1902, in Warsaw, Poland, which was at that time under the occupation of the Russian Empire. He died on October 26, 1983, in Berkeley, California. Alfred was born to the family of Ignacy and Róża (*de domo* Prussak). In 1910 Tarski began to attend the government junior school (Pol. *gimnazjum rządowe*) in Warsaw, and then the 'School of Mazowsze' (Pol. *Szkola Ziemi Mazowieckiej*), also in Warsaw, where he took his graduation exam in 1918. He next studied at the Department of Philosophy of the University of Warsaw under the supervision of Stanislaw Leśniewski (1886–1939); Leśniewski also supervised Tarski's Ph.D. dissertation, which was completed in 1924 and published in Warsaw under the title *O wyrazie pierwotnym w logistyce* (*On the primitive term in logistics*). In

singular reference. For instance, *episi* means 'iron as a substance', while *episi-da* (iron-CLASSIFIER: ROUND) means 'axe' and *episi-kha* (iron-CLASSIFIER:CURVED) means 'wire'. Number agreement is optional for inanimate nouns.

Tarski, Alfred (1902–1983)

P P Chruszczewski, University of Wrocław, Wrocław, Poland

© 2006 Elsevier Ltd. All rights reserved.

Alfred Tarski (Teitelbaum) (1902–1983) was born on January 14, 1902, in Warsaw, Poland, which was at that time under the occupation of the Russian Empire. He died on October 26, 1983, in Berkeley, California. Alfred was born to the family of Ignacy and Róża (*de domo* Prussak). In 1910 Tarski began to attend the government junior school (Pol. *gimnazjum rządowe*) in Warsaw, and then the 'School of Mazowsze' (Pol. *Szkola Ziemi Mazowieckiej*), also in Warsaw, where he took his graduation exam in 1918. He next studied at the Department of Philosophy of the University of Warsaw under the supervision of Stanislaw Leśniewski (1886–1939); Leśniewski also supervised Tarski's Ph.D. dissertation, which was completed in 1924 and published in Warsaw under the title *O wyrazie pierwotnym w logistyce* (*On the primitive term in logistics*). In

1925, Tarski completed his higher doctoral degree (Ger. *Habilitationsschrift*) on the philosophy of mathematics, which also was done at the University of Warsaw. At that time he was lecturing at the University of Warsaw on elementary mathematics and logic and was also teaching mathematics at the Stefan Żeromski High School in Warsaw.

In the 1930s, he began his pioneering work on the concept of truth in formalized languages. Alfred Tarski left Poland in 1939, and World War II made his return to Poland impossible. From 1939 to 1941 he lectured at Harvard University; from 1940 to 1941 he was a visiting professor in New York; and from 1941 to 1942 he was a member of the Princeton University Institute for Advanced Study. In 1942, Tarski started his work at the University of California at Berkeley, where he obtained a position in the Department of Mathematics. There, in 1946, he became Professor of Mathematics, establishing a leading center for research and teaching of mathematical logic.

English was Tarski's seventh language. Polish was his native language; he learned Greek and Latin at school; he studied Russian since a great part of Poland was then under Russian occupation. At the beginning of his career, Tarski published his works in French and in German, as these were the languages of diplomacy and science in those days. After emigrating to the United States, Tarski's lectures as well as his publications were entirely in English.

Tarski taught and was a guest lecturer at a number of foreign universities: Mexico (1957); Los Angeles (1967); Catholic University, Chile (1974–1975), London (1950, 1960), the Sorbonne (1955). In 1957 he was the chairperson of the International Union of History and Philosophy of Sciences. Tarski was also a member of many learned societies, such as the American Academy of Sciences, the American Symbolic Logic Society (chairing the society from 1944 to 1946), the British Academy, and the Royal Dutch Academy of Sciences. He supervised 20 Ph.D. dissertations (among others, Mostowski's, Jónsson's, Lim's, Robinson's, Szmielew's, Thompson's, and Feferman's).

Tarski published more than 300 works and seven books, including *Pojęcie prawdy w językach nauk dedukcyjnych* (*The concept of truth in the languages of deductive sciences*) published by Prace Towarzystwa Naukowego Warszawskiego in Warsaw in 1933. In this work, Tarski elaborated upon a materially adequate and formally correct definition of the 'true sentence.' His results were closely related to Goedel's incompleteness theorem. His other books are *Introduction to logic and to the methodology of deductive sciences* (New York, 1946); *Cardinal algebras* (Oxford, 1949); *Ordinal algebras* (Amsterdam, 1956); *Logic, semantics, metamathematics* (Oxford, 1956); *The completeness of elementary algebra and geometry* (Paris, 1967); and *Cylindric algebras* (Amsterdam, 1971). Between the early 1920s and late 1970s, Tarski published his research results in a number of edited and reviewed volumes and journals in the form of scientific papers, abstracts, summaries, project reports, reviews, and contributions to discussions.

It is generally agreed that Tarski's works gave rise to such disciplines as semantics and the model theory, relating formal symbols to set theoretical constructs and enabling researchers to discuss references of symbols and the truth value of a sentence, as well as the meaning of formal expressions from a more general perspective. Patrick Suppes, Tarski's long-time friend and colleague, noted that as a researcher and lecturer Tarski had a passion for very clear communication, stressing

> the elegance of his thought and talk, the strongly aesthetic feelings that came forth in his presentations and writings. He was really a dazzling lecturer and could explain technical subjects to wide audiences in a very clear and accessible way, starting with very simple ideas, gradually building up a full picture. His papers seem much simpler than they really are, because of his passion for organization and clarity. (cited in Duren *et al.*, 1989: 395).

One of Tarski's students, Solomon Feferman, described him as

> a small person having enormous intensity and vitality, and prodigiously productive. He wrote in a very big, bold hand and spoke with a Polish accent. He was a bit old-fashioned, one had the sense; he stood out in that respect in Berkeley, as a kind of master of the old school. (cited in Duren *et al.*, 1989: 399).

Another of Tarski's students, Jon Barwise (Duren *et al.*, 1989: 397), underlined that it was Tarski who singled out the notion of truth and gave it a mathematical formulation in its own right. This became the basis of model theory, which led to questions concerning cardinalities of models of some theories in the Loewenheim-Skolem-Tarski Theorem, or regarding preservation of truth between different models of some theories in the Los-Tarski Theorem. Alfred Tarski was one of the first to make the notion of domain and truth precise. He established a school of mathematical thought in model theory, and a center for research in logic at the school of mathematical logic at the University of California at Berkeley. It is generally agreed that Tarski's work on decidable and undecidable axiomatic systems also made him a forerunner of computer science.

Location and Speakers

Tatar (*tatar tělě, tatarča*) is the designation for Kazan Tatar and related dialects belonging to the northern subbranch of the Northwestern or Kipchak branch of the Turkic language family. It is distributed over a huge area, from Ryazan in the west to West Siberia in the east, from the Kirov region in the north to Astrakhan in the south. Most Tatar speakers live between the Volga–Kama triangle and the western slopes of southern Ural. The Republic of Tatarstan (*Tatarstan Respublikasi*) with its capital Kazan is situated in the central part of the Russian Federation, at the confluence of the Volga and the Kama. It borders Bashkortostan in the east, Mari El and Udmurtia in the north, and Chuvashia in the west. This multinational republic has a total population of over 3.8 million, mainly consisting of Volga Tatars (over 50%) and Russians (over 40%). There are also speakers of Chuvash, Mordva, Udmurt, Mari, Bashkir, etc.

Speakers of Misher Tatar live mainly west, southwest, and south of the republic. Kasimov Tatar was formerly spoken farther west, in the Ryazan region, on the territory of the old Kasimov Khanate. Tatar-speaking groups, often descendants of Noghays, still live along the Volga river south of the republic, down to the Astrakhan region. There are also scattered Tatar-speaking groups in other central parts of the Russian Federation. About 1 million Tatars live in Bashkortostan. The Tepter Tatars live along the Ural River.

East of the Ural Mountains, in an area that was once the home of sizeable Turkic-speaking groups, West Siberian Tatar varieties of different origins are still spoken by small groups, about 150 000 persons altogether: the dialects of Irtysh, Tümen, Tura, Tobol, Tara, Ishim, etc. The Baraba Tatars, about 8000 persons, live in the Baraba steppe, between Novosibirsk and Omsk. Tatar is also spoken in parts of Kazakhstan, Uzbekistan, China, etc. The total number of Tatar speakers is about 8 million.

The designation 'Tatar' is ambiguous. Until the end of the 19th century, it was used for all languages of Turkic Muslim groups in Russia. It is still used for Crimean Tatar (Judco Crimean Tatar), which is not identical with Volga Tatar, but a language in its own right. The so-called Tatar minority in China, mostly in Xinjiang (about 5000), consists of descendants of Volga and Crimean Tatars. Groups in Poland, Belarus, and Lithuania, referred to as 'Lithuanian Tatars,' are linguistically assimilated descendants of Noghays and Crimean Tatars. The Tatars of West Siberia partly consist of emigrants from the Volga region. The Baraba Tatars go back to deported Kipchak tribes. The Tatars of Astrakhan and Siberia have strong Noghay elements.

Tatar has long been one of the most firmly established Turkic languages. It has consolidated its position further in the post-Soviet era. The official languages of Tatarstan are Tatar and Russian. Of the Tatars of the Russian Federation, 86% regard Tatar as their mother-tongue.

Origin and History

The designation Tatar is first mentioned in Chinese sources and in Turkic inscriptions of the 8th century. Later on it appears as a Mongol tribal name. Kipchak Turkic groups who arrived in the Volga region with the Mongols adopted it for themselves. It was used for the Turkic and Mongol population in the Golden Horde, also for Turkic groups that arrived later, and finally also for older Turkic groups of the Volga–Kama area.

Tatar is a result of complex linguistic contact processes, the main elements being Kipchak Turkic, Volga Bulgar, Volga Finnic, and Mongolic. Turkic

The so-called Tatar minority in China, mostly in Xinjiang (about 5000), consists of descendants of Volga and Crimean Tatars. Groups in Poland, Belarus, and Lithuania, referred to as 'Lithuanian Tatars,' are linguistically assimilated descendants of Noghays and Crimean Tatars. The Tatars of West Siberia partly consist of emigrants from the Volga region. The Baraba Tatars go back to deported Kipchak tribes. The Tatars of Astrakhan and Siberia have strong Noghay elements.

Tatar has long been one of the most firmly established Turkic languages. It has consolidated its position further in the post-Soviet era. The official languages of Tatarstan are Tatar and Russian. Of the Tatars of the Russian Federation, 86% regard Tatar as their mother-tongue.

Origin and History

The designation Tatar is first mentioned in Chinese sources and in Turkic inscriptions of the 8th century. Later on it appears as a Mongol tribal name. Kipchak Turkic groups who arrived in the Volga region with the Mongols adopted it for themselves. It was used for the Turkic and Mongol population in the Golden Horde, also for Turkic groups that arrived later, and finally also for older Turkic groups of the Volga–Kama area.

Tatar is a result of complex linguistic contact processes, the main elements being Kipchak Turkic, Volga Bulgar, Volga Finnic, and Mongolic. Turkic

groups were probably present on the middle course of Volga River from the 5th century on, absorbing local Finno–Ugric tribes of the region. The Volga Bulgar element was of decisive importance. The powerful Volga Bulgar state was created at the end the 9th century and adopted Islam in 922. The Volga Bulgars assimilated native groups of the region. Both Tatars and Chuvash regard themselves as descendants of the Volga Bulgars. The state was destroyed by the Mongols in 1237 and the Khanate of the Golden Horde was established. Its most important element was Kipchak Turkic, which became the dominant assimilating factor. Volga Bulgars, Finno–Ugric groups, and Mongols shifted to Kipchak. The speakers of the predecessor of Chuvash, however, were not assimilated but preserved their language. After the disintegration of the Golden Horde, the Khanates of Kazan, Crimea, Kasimov, Astrakhan, and Sibir were established. The Khanate of Kazan was annexed by Russia in 1552, whereby Tatars, Bashkirs, and Chuvash came under Russian rule. The West Siberian Tatars are partly descendants of Volga Tatars, who left their homeland in this period. A Tatar Autonomous Soviet Republic was established in 1920. After the Soviet era, the Autonomous Republic of Tatarstan became a member of the Russian Federation.

Related Languages and Language Contacts

The Tatar language is related to Bashkir, Crimean Tatar, Kazakh, Karachay–Balkar, Kumyk, Karaim, etc. Tatar has influenced neighboring languages such as Bashkir, Chuvash, and the Finno-Ugric languages Mari (Cheremis), Mordva, and Udmurt (Votyak). The literary language has also had considerable influence on Turkic languages in Central Asia, e.g., Uzbek. Literary Tatar has to a certain extent served as a model for literary Kazakh. Tatar has been influenced by Russian, particularly in the lexicon. The written language was also used by the small Turkic groups of western Siberia, and thus had a strong impact on their dialects.

Certain features typical of Tatar are already found in the Kuman language as attested in the *Codex cumanicus* (14th century), where the language is even referred to as 'Tatar.' The written language used in the cultural centers of the Golden Horde was Khorezmian Turkic, which had its center in Khorezm on the shore of the Aral Sea and was influenced by local Kipchak and Oghuz Turkic dialects.

This tradition was continued in the Khanates that emerged after the fall of the Golden Horde. It was used, with strong Kipchak elements, as the official language in the Crimea up to the 17th century, when it was replaced by Ottoman (Turkish).

Its use in the Khanate of Kazan was strongly influenced by Chaghatay (Chagatai) and Ottoman. A so-called Volga Turki developed, which is often referred to as 'Old Tatar,' though it must be distinguished from older spoken Tatar. It was used for an emerging Tatar literature based on Chaghatay traditions. Religious works were written in this language up to the mid-19th century.

A more genuinely Tatar written language developed in the second part of the 19th century. It was based on the Kazan dialect, though strongly influenced by Chaghatay. It was also used by Mishers and Astrakhan Noghays and, for some decades, Bashkirs. It was of great cultural importance for all Turkic minorities in Russia. At the beginning of the 20th century, Tatar still had a considerable transregional validity. In the Soviet era, it was limited to a regional national language.

Tatar was written with Arabic script until a Roman-based alphabet was introduced in 1927. In 1939, a variant of the Cyrillic alphabet was adopted. The Christian Tatars in the Volga region had used the Cyrillic script already at the end of the 19th century. In the post-Soviet era, a new Roman-based alphabet has been created, although it has not yet replaced the Cyrillic-based script.

Distinctive Features

Tatar exhibits most linguistic features typical of the Turkic family (*see* **Turkic Languages**). It is an agglutinative language with suffixing morphology, sound harmony, and a head-final constituent order. In the following, only a few distinctive features will be dealt with. In the notation of suffixes, capital letters indicate phonetic variation, e.g., *A* = *a/e*. A segment in round brackets only occurs after consonant-final stems. Hyphens are used here to indicate morpheme boundaries.

Phonology

The phonetic basis of modern standard Tatar is Kazan Tatar. The vowel system includes the high-mid vowels *ĕ*, *ŏ*, *ĭ*, *ŏ*, which are shorter and more centralized than the low and high vowels. The vowel *a* of the first syllable is rounded to *å* in the central dialect.

Tatar exhibits the results of systematic vowel shifts. Low vowels of the first syllable have been raised: *e* > *i*, e.g., *min* 'I' (<*men*), *o* > *u*, e.g., *qul* 'arm' (< *qol*), *ö* > *ü*, e.g., *küz* 'eye' (< *köz*). High vowels have been centralized and reduced: *i* > *ĕ*, e.g., *bĕr* 'one,' *u* > *ŏ*, e.g., *qŏš* 'bird' (< *quš*), *ü* > *ŏ*, e.g., *kŏn* 'day' (<*kün*).

Tatar suffixes display front vs. back harmony. The vowel of the suffix depends on the frontness vs. backness of the last stem syllable. The high suffix vowels are *ĕ* and *ĭ*, and the low suffix vowels are *e* and *a*, e.g., *ĕt-ler-ĕbĕz-den* [dog-PL-POSS.1.PL-ABL] (front) 'from our dogs' vs. *at-lar-ĭbĭz-dan* [horse-PL-POSS.1.PL-ABL] (back) 'from our horses.' Rounded vs. unrounded harmony is absent in Standard Tatar, which means that *ŏ*, *ŏ̈*, *u* and *ü* do not occur in suffixes.

Initial *ǰ-* is sometimes found instead of *y-*, mostly in front of *ï* and *i*, e.g., *ǰir* 'place' (cf. Turkish *yer*). In loans originating from Arabic (Arabic, Standard), *ᶜayn* is represented by the voiced fricative *γ*, e.g., *γadet* 'habit' (< *ᶜa:dat*). The consonants that correspond to the affricates *č* and *ǰ* in most other Turkic languages (and are traditionally transcribed so) are pronounced as palatalized fricatives *š′* and *ž′* in Standard Tatar. In front of suffix-initial vowels, stem-final *p*, *q*, and *k* mostly become *b*, *γ*, and *g*, respectively, e.g., *tab-a* [find-PRES] 'finds' vs. *tap* 'find!', *čig-ĕ* [boundary-POSS.3.SG] 'its boundary' vs. *čik* 'boundary.' Various assimilations affect suffix-initial consonants. Thus, the *l* of the plural suffix and the *d* of the ablative suffix are assimilated to *n* after stems ending in nasal consonants, e.g., *uram-nar* [street-PL] 'streets,' *urman-nan* [forest-ABL] 'from the forest.' Nonpermissible consonant clusters are dissolved by means of epenthetic vowels, consonant deletion etc., e.g., *dus* 'friend' vs. *dust-ïm* [friend-POSS.1.SG] 'my friend.'

Grammar

After first- and second-person possessive pronouns the possessive suffix on the head is optional, e.g., *min-ĕm ĕš-ĕm* [I-GEN work-POSS.1.SG] or *min-ĕm ĕš* [I-GEN work] 'my work.' The comparative degree of adjectives takes the suffix *-rAK*, e.g., *ŏzŏn-raq* [long-COMP] 'longer' (cf. Turkish *daha uzun*). The third-person personal pronouns are *ul* 'he, she, it' (with the oblique stem *an-*) and *alar* 'they.' The demonstrative pronouns *bu*, *šušĭ*, *šul*, *tĕgĕ*, *ul* express various degrees of proximity. Approximative numerals are formed with the suffix *-lAp*, e.g., *un-lap* 'approximately ten.'

Tatar has numerous simple and compound aspect-mood-tense forms as well as verbal nouns, converbs, and participles. It has a present tense in *-A* (*-y* after stem-final vowels) plus personal markers, e.g., *kil-e-m[ĕn]* [come-PRES-1.SG] 'I come, I am coming.' The most frequent verbal noun ends in *-(I)w*, e.g., *al-ĭw* 'to take, taking.' An infinitive is formed with *-(I)rGA*, negated *-mAs-kA*. Frequently used converb markers include *-A* (*-y* after stem-final vowels), *-(I)p-* and *-GAč*, e.g., *al-γač* [take-CONV] 'after having taken.' Like most other Turkic languages, Tatar has evidential markers of the type *iken*, e.g., *qayt-qan iken* [return-POSTTERMINAL.PAST EV] 'has obviously returned.' A number of auxiliary verb (postverb) constructions express modifications of the manner of action, e.g., *yan-ïp bĕt-* [burn down-AUX] 'burn down (completely).' Possibility and impossibility are expressed by means of a converb + the auxiliary verb *al-*, e.g., *yaz-a al-* [write-CONV-POSS] 'to be able to write,' *yaz-a al-ma-* [write-CONV-POSS-NEG] 'to be unable to write' (Turkish *yaz-a-bil-* [write-CONV-POSS], *yaz-a-ma-* [write-CONV-POSS-NEG]).

Lexicon

Most basic lexical elements are of Turkic origin. Many loans are of Middle Mongolian, Arabic, Persian, and Russian origin, e.g., *zur* 'big,' *aždaha* 'dragon,' *baqča* 'garden,' *atna* 'week' (Persian), *fikĕr* 'thought,' *taraf* 'side' (Arabic), *stakan* 'glass,' *par* 'steam,' *kuxnya* 'kitchen,' *vrač* 'doctor' (Russian), *uram* 'street,' *dala* 'steppe' (Mongolian). Words of Finno-Ugric origin occur mainly in dialects. Tatar conjunctions are mostly of foreign origin, e.g., *hem* 'and,' *emme* 'but,' *čŏnki* 'for (causal),' *güye* 'as if,' *ki* 'that,' *eger* 'if, when.'

Dialects

Tatar comprises a central dialect group, Kazan Tatar proper. A western dialect group, consisting mainly of Misher Tatar, is spoken in the Volga region outside the republic. An eastern dialect group is spoken in West Siberia. The Irtysh–Tobol dialects hold an intermediate position between Kazan Tatar and other Siberian Tatar dialects. West Siberian dialects often exhibit the changes *č* > *ds* and *ǰ* > *dz* and voicing of intervocalic consonants (like in South Siberia). The vowel shifts are not so strongly developed in these dialects as in Volga Tatar.

Teacher Preparation: Second Language

M Schocker-v. Ditfurth, University of Education Freiburg, Freiburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

History and Developments

Until the 18th century, the teaching of a second language (SL) was in the hands of governesses and language masters, self-taught experts who had developed particular skills of passing their mother tongue on to others. This tradition may account for the high value that has customarily been attributed to native speakers as particularly competent teachers of a second language. The assumption that a native speaker's competence can be considered a quasi-natural and sufficient preparation for language teachers has only recently been called into question (Medgyes, 1994).

The first forms of organized and more systematic teacher preparation emerged at the end of the 19th century, when governments first began to control and regulate education. The preparation for teaching modern languages at first followed the example of teaching Latin and classical Greek, defining the academic study of literature and language as the knowledge base of teachers. Because the study of second languages was then considered to be the privilege of the educated elite, SL teachers predominantly worked in the upper secondary school and in university-bound educational systems or at universities.

The canonization of literature and language studies as the almost exclusive basis for teacher preparation has received growing criticism since the 1960s, when the need for cross-cultural communication as a consequence of worldwide migration and globalization required that many more citizens be able to communicate with speakers of different languages and cultural backgrounds worldwide (Block, 2004). English has become the international language that has established itself alongside local languages in multilingual contexts. This is why in the 1960s and 1970s second languages, mostly English, were introduced to all European citizens in secondary schools as a mandatory part of the curriculum. By the beginning of the 21st century, almost all European countries have mandated SL programs in the primary schools, and most schools require their students to have studied at least two foreign languages by the end of grade 10, with English being the first SL in almost all cases. The Council of Europe (2001) has taken a leading role in promoting and supporting the education of plurilingual citizens by defining plurilingual competence as a prerequisite for European citizenship. It views "users and learners of a language primarily as 'social agents,' i.e., members of society who have tasks. . .to accomplish" (Council of Europe, 2001: 9).

However, the need for SL education is not just a European, but is also a worldwide phenomenon resulting from massive migrations, the spread of communication technology, and economic globalization. This context provides the background against which initiatives to re-conceptualize the knowledge base of language teacher education need to be understood. What a number of critics have put forward since the 1960s has received growing support: teacher education programs often fail to provide the relevant knowledge base that would enable student teachers to prepare their learners adequately for the tasks outlined above and to support them in coping with the complex demands of SL classrooms.

Just as teaching second languages is a highly diverse activity bound to a particular place in time and realized under specific institutional affordances and constraints, so is the preparation of teachers subject to those constraints. One needs to distinguish, for example, between (1) contexts in which, as in most European countries, the state is responsible for teacher education and in which SL learning represents a core (i.e., mandatory) component in school curricula and (2) contexts in which SL learning has the status of a selective subject with little academic prestige. It matters whether the SL is introduced in the primary school as one mandatory subject to be later followed by a third language and whether a student's career depends on achievements in language learning or whether a SL may (or may not) be chosen as an elective. It makes a difference whether the language taught is the dominant language of the school's culture or whether it is a foreign language. Traditionally,

History and Developments

Until the 18th century, the teaching of a second language (SL) was in the hands of governesses and language masters, self-taught experts who had developed particular skills of passing their mother tongue on to others. This tradition may account for the high value that has customarily been attributed to native speakers as particularly competent teachers of a second language. The assumption that a native speaker's competence can be considered a quasi-natural and sufficient preparation for language teachers has only recently been called into question (Medgyes, 1994).

The first forms of organized and more systematic teacher preparation emerged at the end of the 19th century, when governments first began to control and regulate education. The preparation for teaching modern languages at first followed the example of teaching Latin and classical Greek, defining the academic study of literature and language as the knowledge base of teachers. Because the study of second languages was then considered to be the privilege of the educated elite, SL teachers predominantly worked in the upper secondary school and in university-bound educational systems or at universities.

The canonization of literature and language studies as the almost exclusive basis for teacher preparation has received growing criticism since the 1960s, when the need for cross-cultural communication as a consequence of worldwide migration and globalization required that many more citizens be able to communicate with speakers of different languages and cultural backgrounds worldwide (Block, 2004). English has become the international language that has established itself alongside local languages in multilingual contexts. This is why in the 1960s and 1970s second languages, mostly English, were introduced to all European citizens in secondary schools as a mandatory part of the curriculum. By the beginning of the 21st century, almost all European countries have mandated SL programs in the primary schools, and most schools require their students to have studied at least two foreign languages by the end of grade 10, with English being the first SL in almost all cases. The Council of Europe (2001) has taken a leading role in promoting and supporting the education of plurilingual citizens by defining plurilingual competence as a prerequisite for European citizenship. It views "users and learners of a language primarily as 'social agents,' i.e., members of society who have tasks. . .to accomplish" (Council of Europe, 2001: 9).

However, the need for SL education is not just a European, but is also a worldwide phenomenon resulting from massive migrations, the spread of communication technology, and economic globalization. This context provides the background against which initiatives to re-conceptualize the knowledge base of language teacher education need to be understood. What a number of critics have put forward since the 1960s has received growing support: teacher education programs often fail to provide the relevant knowledge base that would enable student teachers to prepare their learners adequately for the tasks outlined above and to support them in coping with the complex demands of SL classrooms.

Just as teaching second languages is a highly diverse activity bound to a particular place in time and realized under specific institutional affordances and constraints, so is the preparation of teachers subject to those constraints. One needs to distinguish, for example, between (1) contexts in which, as in most European countries, the state is responsible for teacher education and in which SL learning represents a core (i.e., mandatory) component in school curricula and (2) contexts in which SL learning has the status of a selective subject with little academic prestige. It matters whether the SL is introduced in the primary school as one mandatory subject to be later followed by a third language and whether a student's career depends on achievements in language learning or whether a SL may (or may not) be chosen as an elective. It makes a difference whether the language taught is the dominant language of the school's culture or whether it is a foreign language. Traditionally,

European SL teachers not only share their learners' common and/or native language but have themselves also been through the process of learning at least one other language, which makes them bilingual or, more often than not, plurilingual. Preparing teachers who can tap a vast resource of personal and collective language learning experiences will certainly be different from preparing those who lack such experiences. Since it is impossible to take these particularities into account when discussing teacher preparation in the following sections, we focus our arguments on the general issues, principles, and developments of SL teacher preparation.

SL Teacher Education: Defining the Knowledge Base

To this day, little is known about why certain teacher education programs are more effective than others. People have been learning to teach languages for a long time, but only a few have tried to understand the processes or the knowledge and experience that underlie effective teacher preparation: "Thus, most conventional practices in language teacher education have operated like hand-me-down stories, folk wisdom shared as 'truths' of the profession with little other than habit and convention on which to base them" (Freeman, 1996: 351). What we do know, however, supports personal anecdotal observation: The dominant teaching formats at many universities are transmission oriented and, therefore, contradict current ideas of student-centeredness and communicative, task-based methodology, as outlined in Legutke and Thomas (1993) or Ellis (2003). Program components lack a coherent curriculum framework, and to a large extent they fail to integrate courses in education, psychology, or sociology, for example. The practicum, if provided at all, often remains an alien element among university courses. Only in recent years has there been a growing interest in reconceptualizing the knowledge base for SL teacher education (Richards and Nunan, 1990; Richards and Lockhart, 1994; Freeman and Johnson, 1998), which has resulted in an investigation of teacher learning and development in authentic SL learning contexts (see Appel, 1995; Freeman and Richards, 1996; Appel, 2000; Schocker-v. Ditfurth, 2001; Caspari, 2003; Tsui, 2003).

Taking Account of the Complexity of SL Teaching and Learning

Despite this growing interest in SL teaching, we must acknowledge that the "knowledge base is hardly as clearly defined or as widely held as it is in other professions such as law, medicine, accountancy, and architecture" (Freeman and Johnson, 2004: 121). This is because the subject matter for SL teaching covers a heterogeneous field and involves different disciplines, research approaches, contexts of practice, learners and teachers, and social settings. However, unless we *do* agree on a clear idea of what SL teachers need to know and how professional knowledge, skills, and attitudes are developed, the field of SL teaching will not establish itself as a professional, recognized field of study nor will we be able to improve its implementation. The situation becomes even more complex if we include the many changes that have occurred in the last 50 years in the way we view language, language acquisition, the language learner, language teaching methods, and the language teacher. These changes are shown clearly in a historical review undertaken by Larsen-Freeman (1998; see Table 1).

Larsen-Freeman is surely correct in arguing that all of these approaches have some merit, but that none of them reflects the whole picture. This is why she reached this conclusion: rather than search for the one right point of view, "we must redirect the nature of our inquiry to search for wholeness—for more complete understanding of the many facets that comprise these basic constructs in our field. Being aware of the complexity has tremendous implications for how we train teachers" (Larsen-Freeman, 1998: 4). Therefore, as a first step, we need to prepare our student teachers to enable them to understand the complexity of SL teaching and learning in authentic contexts of practice.

Basing Teacher Education on Teaching and on the Person Who Teaches

There is a traditional misconception that all it takes to become a competent SL teacher is to know about relevant publications. Yet, professional action in dynamic situations of practice, such as in a classroom, is characterized by such features as uncertainty, complexity, uniqueness, instability, and value conflict (Schön, 1983). This is why teachers cannot be adequately prepared for their job just by reading relevant disciplinary knowledge. Following Schön (1983) and Freeman and Johnson (1998), we argue that the knowledge base must focus on the activity of teaching itself and on the contexts in which it is done. It must also focus on the person who teaches, because unless knowledge (from whatever source) becomes part of student teachers' ideas of their professional selves, it will not contribute to the quality of learning second languages: SL teachers generate their own personal theories on SL learning that are based on their own language learning experiences and their experiences in particular teaching contexts. Therefore, it would

Table 1 A historical review of language teaching

Linguistics	*Language acquisition*	*Language learner*	*Language teaching*	*Language teacher*
Structural	Habit formation Behaviorism	Mimic	Dialogues Patterns Practice Drills	Performer Model Conductor Cheer leader

Critical	Experiential	Political being	Critical Pedagogy Participatory approach Problem posing	Advocate

From Larsen-Freeman, 1998: 4.

be wrong to assume that teachers can be viewed as mere consumers of ideas that have been developed outside language classrooms in related disciplines and may simply be transmitted to them. In the following sections, we ground this basic assumption on relevant research, drawing on learning-to-teach studies and studies on the nature and development of expertise in SL teaching and learning.

The Teacher Learner: How Do Student Teachers Learn to Teach? The views on what counts as professional education can be classified into three major models, according to Wallace (1991). They are described in chronological order, along with the contributions made to each model by research into learning to teach.

Craft Model: Learning as Imitation of a 'Master Teacher' or the Expert Teacher as Model In the craft model, the student teacher learns by imitating the techniques of an experienced professional practitioner and by following his or her instructions and advice. Professional competence is seen as the passing on of expertise from generation to generation. This model is shown in Figure 1.

The drawback to this model is obvious: It does not capture developments in dynamic societies, where change is a basic feature. However, the relevance of the idea of teachers as models should not be dismissed completely. We know from various learning-to-teach studies that student teachers begin their education with images of teaching that they have acquired during their own (language) learning experiences as students (Kagan, 1992; Johnson, 1994). Lortie (1975) termed this process "the apprenticeship of observation." This apprenticeship shapes student teachers' dispositions regarding how to act in the classroom, even if contrary to whatever cognitive knowledge they may have encountered during teacher education. Unless student teachers encounter practice situations in which they experience convincing alternative practices by observing an expert teacher, these imprints are very resistant to change (see results in Schocker-v. Ditfurth, 2001). Student teachers find readings on new approaches to teaching convincing, in regard to their theoretical rationale, but not credible because they cannot imagine how to apply the alternatives about which they read. This is why Fullan is correct in writing that "(t)he main reason for the failure of teacher programs is that they are based on extremely

Figure 1 The craft model of professional education. From Wallace, 1991: 6.

vague conceptions. Having an ideology is not the same as having conceptions and ideas of what should be done and how it should be done" (Fullan, 1993: 109).

Student teachers need to see how it can be done in order to be able to develop alternative and more appropriate images of teaching. Therefore, teacher educators need to be positive role models from whom students gradually learn by appropriating the mutually agreed-upon purposes and corresponding practices. However, this concept of 'teacher as model' must not be confused with the mechanical imitation of behavior, which characterizes behaviorist-based teaching. Instead, it is understood in the Vygotskyan sense of learning as relational imitation, expressed in his concept of "the zone of proximal development" (Vygotsky, 1978).

Applied Science Model: Learning as Application of Knowledge The applied science model is probably still the most prevalent model underlying teacher education programs. According to this model, practical knowledge may be developed by the application of scientific knowledge that is conveyed or transmitted to student teachers (in lectures, for example) by those who are experts in the relevant areas. It is up to the recipients of this knowledge to apply the scientific findings by putting them into practice (see Figure 2).

This classical research-development-dissemination (RDD) model of innovation assumes that there are general solutions to practical problems, that these solutions may be developed outside practical situations (at universities, for example), and that solutions can be translated into teachers' actions by means of publications, training, administrative orders, and the like (Schön, 1983). This model ignores the knowledge that student teachers have acquired during their many years as (language) learners (see above), and it does not capture the nature and development of professional competence. It assumes an almost complete separation between research and practice and between those who think and those who do. Through this division of labor, a hierarchy of different kinds of knowledge is established, which reflects a mistrust

Figure 2 The applied science model of professional education. From Wallace, 1991: 9.

of practitioners who are then reduced merely to applying what has been predefined in the academic and administrative power structure above them.

However, not all the research meant to provide a deeper understanding of SL teaching and learning is relevant for teachers. Appel (1995: xi) illustrated this point when he described how he perceived the relevance of research when he was a novice teacher:

> "Everyday life at school was not about research. Research is controlling the variables; teaching is being controlled by them. At my workplace [secondary school SL classroom] no factors could be isolated. On the contrary, they were hopelessly muddled. Research was about keeping things separate. Life meant everything at once. . . .Research was about being rigorous and consistent. Life was about survival by any available means."

Reflective Model: 'Reflected Practice' to Develop Appropriate Practical Knowledge When teacher educators refer to professional knowledge, they often talk about research-based disciplinary knowledge, which usually forms the basis of teacher education programs for SL teachers. However, it would be impossible to cope with the complex demands of SL classrooms on the basis solely of a conscious application of principles alone, as has been suggested by the applied science model. This idea of teaching as decision making does not capture the whole picture. To be able to cope in complex contexts of practice, another type of knowledge, which Wallace (1991) has called "experiential knowledge" and which Schön (1983)

Figure 3 The reflective model of professional education. From Wallace, 1991: 15.

has described as "tacit knowledge in action," is relevant: to be able to cope with the sheer complexity and fluidity of classroom interaction, teachers need routines that will allow them to act competently in a classroom (see Figure 3).

Routines are part of a teacher's practical knowledge. They have been built up through frequent repetitions, and they are executed largely unconsciously. This is why practitioners are often unable to describe their practical knowledge. Because student teachers cannot fall back on corresponding routines, they find it hard to manage the complexity of processes in SL classrooms. It is, therefore, important that they develop their experiential knowledge in authentic practical contexts, so that they gain the opportunity to develop appropriate routines and to put their personal practical theories to the test by putting them through a continuous cycle of action and reflection, as this model suggests. We agree with Tsui (2003: 257) who argued that it is necessary for teachers to be able to articulate this tacit knowing-in-action because the ability to reflect on one's teaching and to share and develop it with the professional community is an aspect of expertise in teaching. Therefore, student teachers need opportunities to develop expertise both by observing expert teachers and by doing their own classroom-based teaching projects.

However, student teachers "are not empty vessels waiting to be filled with theoretical and pedagogical skills. They are individuals who enter teacher education programs with prior experiences, personal values, and beliefs that inform their knowledge about teaching and shape what they do" (Freeman and Johnson, 1998: 401). When teaching for the first time, these prior experiences find expression in classroom routines that they have established as part of their 'apprenticeship of observation.' A learning-to-teach study from the German context (Schocker-v. Ditfurth, 2001) was able to clearly identify the origin of some of these routines (such as the opening of lessons, the use of linguistic markers to lead in a new activity, or even the use of gestures to allocate talking time to students) as being rooted in their own language learning experiences as students. In discussions about their videotaped lessons with their tutor, student teachers became aware of the fact that they had acquired these routines from their former language teachers' repertoire, which they had copied unconsciously while simultaneously rejecting them intellectually.

The Context: What Is the Role of the SL Learning Classroom in Teacher Education?

As we have already demonstrated, it is crucial to include the SL learning classroom into teacher education for various reasons. From studies into teacher knowledge (Appel, 2000) we know that the appropriateness of materials and tasks depends on the perceived value that teachers and their learners associate with them. It is their interactions in the classroom that determine what is made available to be learned. This concept is expressed in the idea of the SL classroom as a 'culture' with particular features that affect the contents and structure of communication: a language class "is an arena of subjective and intersubjective realities which are worked out, changed, and maintained. And these realities are not a trivial background to the tasks of teaching and learning a language. They locate and define the new language itself...and they continually...mold the activities of teaching and learning" (Breen, 1985: 142). This is why Breen's distinction between *task-as-work plan* and *task-in-process* is crucial: Teachers need to be aware of the processes that a task triggers with their learners because the quality and efficacy of a task depend on its use during teaching and learning. Freeman and Johnson are, therefore, correct when they described schools as "powerful places that create and sustain meanings and values.... Thus, it is misleading to see them merely as settings in which educational practices are implemented .... Instead, ... schools and classrooms function as frameworks of value and interpretation in which language teachers must learn to work effectively" (Freeman and

Johnson, 1998: 409). The centrality of the classroom has been confirmed by a recent study on the expertise of ESL teachers (Tsui, 2003): teachers' conceptions and understanding of teaching are grounded and developed in their specific contexts of work. Moreover, their knowledge may not be delineated as separate domains of knowledge; rather, these knowledge domains are 'intermeshed' (Tsui, 2003: 247).

Published Knowledge: What Disciplines Constitute Relevant Subject Matter?

It probably comes as no surprise that attempts to agree on a common definition of what counts as relevant disciplinary knowledge and subject matter for SL teaching and learning have largely failed. The recent commentaries on re-conceptualizing teacher education in the *TESOL Quarterly's* forum (see Yates and Muchisky, 2003; Freeman and Johnson, 2004) are indicative of this state of affairs. Before we turn our attention to the practical consequences this complexity has on organizing learning in teacher education, we give a brief survey of the relevant disciplines as defined in Bausch *et al.* (2003). We subscribe to Freeman and Johnson's (2004: 125) view of SL teaching as not being a discipline but rather, very much like education, "a field of activity" that draws on various disciplines. These disciplines include linguistics, SL acquisition, philosophy of education, learning theory and psychology, literary studies, and cultural studies.

- *Linguistics:* Linguistics describes languages as systems of human communication. This discipline covers many different areas of investigation; for example, sound systems (phonetics, phonology), the study of the basic meaningful forms in language (morphology), sentence structure (syntax), meaning systems (semantics), and how language is used in social contexts (pragmatics, discourse analysis, sociolinguistics). Student teachers need to know not only linguistic subject matter knowledge about the language but also the pedagogical content knowledge (Calderhead, 1991) and the skills it takes to be able to mediate the language to learners. For example, they need to know about and be able to use appropriate interactive strategies, strategies to mediate the meaning of words, appropriate (corrective) feedback to learners, and appropriate language use in tasks. "(A)ny description of the English languages content must be understood against the backdrop of teachers' professional lives, within the settings where they work and within the circumstances of that work" (Freeman and Johnson, 1998: 405). Student teachers need to experience and make sense of what language is, how it is learned, and how this knowledge leads to certain instructional activities that support their learning (Freeman and Johnson, 2004).
- *SL Acquisition:* SL acquisition research investigates how second or foreign languages are learned. Researchers approach the question from different perspectives, but agree that language learning is a dynamic and multidimensional process, which is why sociocultural approaches to researching language acquisition seem more appropriate (on the relevance of SL acquisition theory for language teachers, see Ellis, 2003; Freeman and Johnson, 2004).
- *Philosophy of Education:* Philosophy of education discusses the general principles and purposes of human education, of which the learning of foreign languages is a part. One of these principles, for example, is learner autonomy, which is characterized as the motivation to take charge of one's own learning. To do so, learners need to be able and willing to act independently and in cooperation with others – an attitude that should be fostered in SL classrooms as well.
- *Learning Theory and Psychology:* This discipline describes how and why people learn. For example, it investigates the cognitive differences in the ways individuals learn (= learning styles) and highlights the need for teachers to take these differences into account. It focuses on the relationship between language learning and the age of acquisition or factors affecting the motivation to learn (see Cameron, 2001). This discipline investigates group dynamics and teacher and learner roles and identities.
- *Literary Studies:* This discipline discusses the nature of literary texts as one form of communication. It explores the factors that constitute this type communication, such as the author, the written text, and the reader.
- *Cultural Studies:* This discipline analyzes cultural phenomena and the way they represent cultural meaning. It looks at how representations of cultures are defined by issues of race, gender, and class and incorporates a historical perspective into the analysis. It also considers the process of relating different cultures (intercultural learning).

Principles for Designing and Evaluating Teacher Education Programs

Teachers have to cope with complex demands in SL classrooms. Research on the nature of teaching and findings from learning-to-teach studies suggest that teacher education is best organized according to the following three principles.

Research Approach to Learning: Developing a Multiperspective View on the SL Classroom

To help them understand the complex dynamics that determine language learning in SL classrooms, student teachers learn to develop a research approach to SL learning. They learn to integrate the relevant perspectives on learning and teaching. These perspectives include three domains of knowledge: relevant published knowledge, student teachers' own perspectives on language learning, and the perspective of the practical context.

Experiential Learning: Developing Action-Oriented Models for SL Classrooms

Teacher preparation courses are organized in a way that allows student teachers to experience the very processes that they are supposed to initiate with students in their prospective classrooms: the way learning is organized in these courses corresponds with the conditions of learning they are supposed to create in their prospective classroom. For example, when a course explores the potential of project work for SL learning, student teachers cooperate in teams, choose a research question, use various resources to do their research, discuss and publish the results of their projects, use the target language as their language of communication, and evaluate selected aspects of the process and the product of their cooperation according to mutually negotiated criteria. In doing all of this, they experience the advantages and the drawbacks of cooperative learning. It is hoped that, in this way, they will gradually appropriate the multiple skills that this complex SL learning environment entails.

Experimental Learning: Developing Context-Related Competencies through Cooperation in Cross-Institutional Projects

The ability to develop a research approach to language classrooms implies that teacher preparation needs to overcome the traditional separation of the institutions of school and university. The tradition of language teaching at schools often follows the structure of a textbook and a routine sequence of presentation, practice, and production. This organization of the language learning process often clashes with less controlled, learning-centered approaches to SL teaching and learning, such as the task-based approach (Ellis, 2003). Student teachers need what has come to be called 'dynamic qualifications'; that is, competencies and value judgments, which are the basis for any innovation to be successful. Such competencies include an appreciation of problems that one has identified during the learning process and student orientation, the ability to evaluate one's work, an experimental attitude to practice, and the ability to cope with controlled risks (see Schocker-v. Ditfurth, 2001). This approach is in line with Tsui's research on teacher expertise. It is a characteristic of an expert teacher to be oriented to 'problematization'; that is, the ability to identify and define problems and then to tackle them (Tsui, 2003: 272). For example, student teacher preparation courses that are suitable for developing this attitude focus on the use of technology for SL learning, during which student teachers develop innovative materials and tasks for SL classrooms in cooperation with teachers who are not used to integrating technology in their classroom; or they evaluate textbooks against criteria of task-based language learning, develop alternative tasks, and discuss their findings with the publishers of these textbooks. These examples show that, up to a point, student teachers are proactive persons, agents of change, who develop certain aspects of classroom language learning for a particular and clearly defined context (Schocker-v. Ditfurth and Legutke, 2002).

Models of Teacher Education Environments

Practicum as a Core Component of a Teacher Education Environment

The most radical implementation of a research approach to teacher education is realized within the framework of a practicum. The practicum is no longer simply an addition to the general teacher preparation course work, but rather constitutes its core component. The relevant course work devoted to introducing future teachers to issues of SL teaching, design of materials, and language analysis feeds into the practicum and/or derives its major content from the practicum experience (Schocker-v. Ditfurth, 2001).

In a first sequence of task-driven activities, student teachers are introduced to problematized fundamental constructs and issues of SL learning from published knowledge. They then connect these constructs to their own language learning experiences as language learners in school, thereby exploring their particular apprenticeship of observation. Second, student teachers explore some of these constructs and issues through classroom observation, which, together with the literature discussed in the first phase, provides the basis for interviews of the teachers observed. This approach triggers discussions on the relevance of the constructs; the appropriateness of content and processes for specific groups of language learners; and the choice of materials, tasks, and means of assessment, and the like. Pedagogical content knowledge, therefore, is not misunderstood

as prescriptive knowledge to be applied in practice. Rather, through the learning tasks, a personal and critical reflection on the relevance of the pedagogical content knowledge is fostered, supporting the emergence of a personally plausible and contextually acceptable theory of SL learning. During the last third of this type of integrated practicum, student teachers pursue one personally relevant research question that they try to answer by taking into account both published knowledge and their teaching experience. They are also encouraged to include the view of their learners and the teacher. Using a variety of methods of data gathering and appropriate modes of data analysis, they finally prepare a public presentation of their findings for those students who will follow them in a new cycle of teacher preparation.

Learning Environments with a Classroom-Based Research Component

In this type of learning-to-teach environment, a university course is a core component that is extended by contact with a number of foreign language/second language classrooms in which teachers participate in the teacher preparation work through face-to-face encounters and/or through the Internet. At the same time, the student teachers become part of the school classroom for some time through personal participation and regular communication with the teacher and the SL learners. Student teachers working in self-directed and cooperative groups prepare theme-centered project scenarios that they put into practice in their partner classrooms while pursuing a clearly defined set of appropriate research questions. During the implementation phase, student teachers become responsible for a small group of SL learners (up to five learners) at a time.

What is important in this type of learning environment is that the student teachers learn to navigate various discourses. Seminar discourse requires student teachers to interact with teacher educators, their fellow students, and also their team members on the content and processes of their projects and the appropriate research approach. This discourse, conducted in the target language, is enriched by input from cooperating teachers. At the level of classroom discourse, student teachers have to interact with their partner teachers and with the groups of SL learners they are responsible for during the implementation of their projects. At this level of discourse, student teachers can explore the differences between what seems predictable and doable at the level of seminar discourse and what often proves to be highly unpredictable, and sometimes questionable, in the classroom. Such a research-oriented learning environment counteracts established teacher preparation practice, which exposes students to constructs and theories without giving them a chance to experience its relevance and reflect on its potential for SL learning.

Learning Environments with an Indirect Research Component

The environment with a classroom-based research component described above is very demanding for all parties involved when compared to established teacher preparation coursework. In addition, the systematic cooperation with schools and teachers that it requires is not always easy to realize. Consequently, an alternative is for student teachers to work with classroom data gathered in previous projects. All the data generated – that is, video data from classroom projects, interviews with teachers and students, and log-files of the communication between cooperating teachers and teacher students – can be explored as a means of grappling with and understanding the complexity of language classrooms. As in the previous learning environment, students are simultaneously exposed to appropriate and relevant published knowledge, providing conceptual frameworks to be used when trying to make sense of the data or to be reassessed in view of the classroom data.

Learning Environments Using Participant Observation in Classrooms and/or Video Documents

A further mode of research-oriented teacher preparation can be realized by systematically integrating task-based classroom observations that include the multiple perspectives of the teacher and his or her SL learners. The explorations and presentations of student teachers' perspectives on classrooms in action can be jointly compared to interpretations offered by the teacher and learners. Such interpretative work, again further enriched by published knowledge, can be an important step toward helping student teachers develop their professional selves as teachers.

The models outlined above are not mutually exclusive, but rather are fundamental building blocks of any teacher preparation program, which supplement each other to contribute to the education of student teachers on their journey to becoming professional SL teachers.

Perspectives and Developments

To do justice to the complexity of the factors involved in language learning, it is necessary to foster

a multiperspective view on teacher education, which currently does not define mainstream teacher education practice. In addition, there is a need to think of ways to individualize learning, to take into account differing degrees of experience and commitment of student teachers, thus fostering their engagement in understanding the learning process and promoting critical reflection. A teaching portfolio documenting students' reflections on their learning processes, which some universities have started to introduce, is certainly a possible means toward these goals. What Freeman and Johnson formulate for the teaching of English as a second language (TESOL) and the preparation of teachers of English applies to SL teaching in general: strengthening and improving TESOL presupposes a conceptual clarity about what constitutes TESOL as a field of activity. "Such clarity calls for a more profound and reasoned understanding of what language teachers need to know to do what they do, how these skills and knowledge are learned in professional preparation and through professional development, and how they are practiced with students in classrooms" (Freeman and Johnson, 2004: 125). Such profound and reasoned understanding needs to include substantial research into the beliefs and practices of all components of teacher preparation: Applied linguists, experts in SL acquisition, and professors of literature and cultural studies have always reasserted the importance of their disciplines for teacher preparation without ever having engaged in the research of their own practice – their own classrooms – that are designed, managed, and maintained to contribute to the preparation of teachers (Bartels, 2002).

Teaching of Minority Languages

G Extra and K Yağmur, University of Tilburg, Tilburg, The Netherlands

Focus and Nomenclature

Europe has a rich diversity of languages (Haarmann, 1975). This fact is usually illustrated by reference to the national languages of Europe. However, many more languages are spoken by the inhabitants of Europe. Examples of such languages are Welsh and Basque, or Arabic and Turkish. These languages are usually referred to as minority languages, even when in Europe as a whole there is no one majority language because all languages are spoken by a numerical minority. The languages referred to are representatives of regional minority (RM) and immigrant minority (IM) languages, respectively.

RM and IM languages have much in common, much more than is usually thought. On their sociolinguistic, educational, and political agendas, we find issues such as their actual spread; their domestic and public vitality; the processes and determinants of language maintenance versus language shift towards majority languages; the relationship between language, ethnicity, and identity; and the status of minority languages in schools, in particular in the compulsory stages of primary and secondary education. The origin of most RM languages as **minority** languages lies in the 19th century, when, during the processes of state formation in Europe, they found themselves excluded from the state level, in particular from general education. Only in the last few decades have some of these RM languages become relatively well protected in legal terms, as well as by affirmative educational policies and programs, both at the level of various nation-states and at the level of the European Union (EU) (see 'Beyond Bilingualism' below).

There have always been speakers of IM languages in Europe, but these languages have emerged only recently as community languages spoken on a wide scale in northwestern Europe, due to intensified processes of migration and minorization. Turkish and Arabic are good examples of so-called 'non-European' languages that are spoken and learned by millions of inhabitants of the EU member states. Although IM languages are often conceived of and transmitted as core values by IM language groups, they are much less protected than RM languages by affirmative action and legal measures in, for example, education. In fact, the learning and certainly the teaching of IM languages are often seen by speakers of mainstream languages and by policy makers as obstacles to integration. At the European level, guidelines and directives regarding IM languages are scant and outdated.

Despite the possibilities and challenges of comparing the status of RM and IM languages, amazingly few connections have been made in the sociolinguistic, educational, and political domains. In the Linguistic Minorities Project of the early 1980s, which was restricted to England, an observation was made which still applies to the situation today: "The project has been struck by how little contact there still is between researchers and practitioners working in bilingual areas and school systems, even between England and Wales. Many of the newer minorities in England could benefit from the Welsh experience and expertise" (LMP, 1985: 12). In our opinion, little has improved over the past decades, and contacts between researchers and policy makers working with different types of minority groups are still scarce. Examples of publications which focus on both types of minority language are the dual volumes on RM and IM languages by Alladina and Edwards (1991), and more recently the integrated volumes by Ammerlaan *et al.* (2001) and Extra and Gorter (2001).

As yet, we lack a common referential framework for the languages under discussion. As all of these RM and IM languages are spoken by different language communities and not at statewide level, it may seem logical to refer to them as community languages, thus

Focus and Nomenclature

Europe has a rich diversity of languages (Haarmann, 1975). This fact is usually illustrated by reference to the national languages of Europe. However, many more languages are spoken by the inhabitants of Europe. Examples of such languages are Welsh and Basque, or Arabic and Turkish. These languages are usually referred to as minority languages, even when in Europe as a whole there is no one majority language because all languages are spoken by a numerical minority. The languages referred to are representatives of regional minority (RM) and immigrant minority (IM) languages, respectively.

RM and IM languages have much in common, much more than is usually thought. On their sociolinguistic, educational, and political agendas, we find issues such as their actual spread; their domestic and public vitality; the processes and determinants of language maintenance versus language shift towards majority languages; the relationship between language, ethnicity, and identity; and the status of minority languages in schools, in particular in the compulsory stages of primary and secondary education. The origin of most RM languages as **minority** languages lies in the 19th century, when, during the processes of state formation in Europe, they found themselves excluded from the state level, in particular from general education. Only in the last few decades have some of these RM languages become relatively well protected in legal terms, as well as by affirmative educational policies and programs, both at the level of various nation-states and at the level of the European Union (EU) (see 'Beyond Bilingualism' below).

There have always been speakers of IM languages in Europe, but these languages have emerged only recently as community languages spoken on a wide scale in northwestern Europe, due to intensified processes of migration and minorization. Turkish and Arabic are good examples of so-called 'non-European' languages that are spoken and learned by millions of inhabitants of the EU member states. Although IM languages are often conceived of and transmitted as core values by IM language groups, they are much less protected than RM languages by affirmative action and legal measures in, for example, education. In fact, the learning and certainly the teaching of IM languages are often seen by speakers of mainstream languages and by policy makers as obstacles to integration. At the European level, guidelines and directives regarding IM languages are scant and outdated.

Despite the possibilities and challenges of comparing the status of RM and IM languages, amazingly few connections have been made in the sociolinguistic, educational, and political domains. In the Linguistic Minorities Project of the early 1980s, which was restricted to England, an observation was made which still applies to the situation today: "The project has been struck by how little contact there still is between researchers and practitioners working in bilingual areas and school systems, even between England and Wales. Many of the newer minorities in England could benefit from the Welsh experience and expertise" (LMP, 1985: 12). In our opinion, little has improved over the past decades, and contacts between researchers and policy makers working with different types of minority groups are still scarce. Examples of publications which focus on both types of minority language are the dual volumes on RM and IM languages by Alladina and Edwards (1991), and more recently the integrated volumes by Ammerlaan *et al.* (2001) and Extra and Gorter (2001).

As yet, we lack a common referential framework for the languages under discussion. As all of these RM and IM languages are spoken by different language communities and not at statewide level, it may seem logical to refer to them as community languages, thus

contrasting them with the official languages of European nation-states. However, the designation 'community languages' is already in use to refer to the official languages of the EU, and in that sense occupied territory. From an inventory of the different terms in use, we learn that there are no standardized designations for these languages across nation-states. Table 1 gives a nonexhaustive overview of the nomenclature of our field of concern in terms of reference to the people, their languages, and the teaching of these languages. The concept of 'lesser-used languages' has been adopted at the EU level; the European Bureau for Lesser Used Languages, established in Brussels and Dublin, speaks and acts on behalf of 'the autochthonous regional and minority languages of the EU.' Table 1 shows that the utilized terminology varies not only across different nation-states, but also across different types of education.

Table 1 Nomenclature of the Field

Reference to the People

- nonnational residents
- foreigners, *étrangers*, *Ausländer*
- (im)migrants
- newcomers, new Xmen (e.g., new Dutchmen)
- cocitizens (instead of citizens)
- ethnic/cultural/ethnocultural minorities
- linguistic minorities
- allochthones (e.g., in the Netherlands), allophones (e.g., in Canada)
- non-English-speaking (NES) residents (in particular in the USA)
- *anderstaligen* (Dutch: those who speak other languages)
- colored/black people, visible minorities (the latter in particular in Canada)

Reference to their Languages

- community languages (in Europe versus Australia)
- ancestral/heritage languages (common concept in Canada)
- national/historical/regional/indigenous minority languages versus nonterritorial/nonregional/nonindigenous/ non-European minority languages
- autochthonous versus allochthonous minority languages
- lesser used/less widely used/less widely taught languages (in EBLUL context)
- stateless/diaspora languages (in particular used for Romani)
- languages other than English (LOTE: common concept in Australia)

Reference to the Teaching of These Languages

- instruction in own language (and culture)
- mother tongue teaching (MTT)
- home language instruction (HLI)
- community language teaching (CLT)
- regional minority language instruction versus immigrant minority language instruction
- *enseignement des langues et cultures d'origine* (ELCO: in French/ Spanish primary schools)
- *enseignement des langues vivantes* (ELV: in French/Spanish secondary schools)
- *muttersprachlicher Unterricht* (MSU: in German primary schools)
- *muttersprachlicher Ergänzungsunterricht* (in German primary/ secondary schools)
- *herkunftssprachlicher Unterricht* (in German primary/secondary schools)

Source: Extra and Yağmur (2004: 19).

There is much published evidence on the status and use of RM languages, both in Europe and abroad (e.g., Gorter *et al.*, 1990; *see also* **Minorities and Language**). Baetens Beardsmore (1993) focused on RM languages in western Europe, whereas the focus of Synak and Wicherkiewicz (1997), Bratt-Paulston and Peckham (1998), and Hogan-Brun and Wolff (2003) was on RM languages in central and eastern Europe. Given the overwhelming focus on mainstream language acquisition by IM groups, there is much less evidence on the status and use of IM languages across Europe as a result of processes of immigration and minorization. In contrast to RM languages, IM languages have no established status in terms of period and area of residence. Obviously, typological differences between IM languages across EU member states do exist, e.g., in terms of the status of IM languages as EU languages or non-EU languages, or as languages of formerly colonialized source countries. Taken from the latter perspective, Indian languages are prominent in Great Britain, Maghreb languages in France, Congolese languages in Belgium, and Surinamese languages in the Netherlands.

Tosi (1984) offered an early case study on Italian as an IM language in Great Britain. Most studies of IM languages in Europe have focused on a spectrum of IM languages at the level of one particular multilingual city (Kroon, 1990; Baker and Eversley, 2000), one particular nation-state (LMP, 1985; Alladina and Edwards, 1991; Extra and Verhoeven, 1993a; Caubet *et al.*, 2002; Extra *et al.*, 2002), or one particular IM language at the European level (Tilmatine, 1997 and Obdeijn and De Ruiter, 1998 on Arabic in Europe, or Jørgensen, 2003 on Turkish in Europe).

A number of studies have taken both a crossnational and a crosslinguistic perspective on the status and use of IM languages in Europe (e.g., Husén and Opper, 1983; Jaspaert and Kroon, 1991, Extra and Verhoeven, 1993b, 1998; Extra and Gorter, 2001). Churchill (1986) offered an early crossnational perspective on the education of IM children in the OECD countries, whereas Reid and Reich (1992) carried out a crossnational evaluative study of 15 pilot projects on the education of IM children supported by the European Commission.

Crossnational Perspectives on Community Language Teaching

Across Europe, large contrasts occur in the status of IM languages at school, depending on particular

nation-states, or even particular federal states within nation-states (as in Germany), and depending on particular IM languages being national languages in other European (Union) countries or not. Most commonly, IM languages are not part of mainstream education. In Great Britain, for example, IM languages are not part of the so-called national curriculum, and they are dealt with in various types of so-called complementary education in out-of-school hours (see e.g., Martin *et al*., 2004).

Here we present the most salient outcomes of the Multilingual Cities Project (MCP), a multiple case study in six major multicultural cities in different EU member states (Extra and Yağmur, 2004). The aims of the MCP were to gather, analyze, and compare multiple data on the status of IM languages at home and at school. In the participating cities, ranging from northern to southern Europe, Germanic and/or Romance languages have a dominant status in public life. Figure 1 gives an outline of the project.

Being aware of crossnational differences in denotation (see Table 1), we use the concept of community language teaching (CLT) when referring to this type of education. Our rationale for using the concept of CLT rather than the concepts of mother tongue teaching or home language instruction is the inclusion of a broad spectrum of potential target groups. First of all, the status of an IM language as a 'native' or 'home' language can change through intergenerational processes of language shift. Moreover, in secondary education, both minority and majority pupils are often *de jure* (although seldom *de facto*) admitted to CLT (in the Netherlands, for instance, Turkish is a secondary school subject referred to as 'Turkish' rather than 'home language instruction'; compare also the concepts of *enseignement des langues et cultures d'origine* and *enseignement des langues vivantes* in French primary and secondary schools in Table 1, respectively).

In all countries involved in the MCP, there has been an increase in the number of IM pupils who speak a language at home other than or in addition to the mainstream language in primary and secondary education. Schools have largely responded to this home–school language mismatch by paying more attention to the learning and teaching of the mainstream language as a second language. A great deal of energy and money is being spent on developing curricula, teaching materials, and teacher training for second-language education. CLT stands in stark contrast to this, as it is much more susceptible to an ideological debate about its legitimacy. While there is consensus about the necessity of investing in second-language education for IM pupils, there is a lack of support for CLT. IM languages are commonly considered sources of problems and deficiencies, and they are rarely seen as sources of knowledge and enrichment. Policy makers, local educational authorities, school principals, and teachers of 'regular' subjects often have reservations or negative attitudes towards CLT. On the other hand, parents of IM pupils, CLT teachers, and IM organizations often make a case for including IM languages in the school curriculum. These differences in top-down and bottom-up attitudes were found in all the cities and countries investigated.

From a historical point of view, most of the countries show a similar chronological development in their argumentation in favor of CLT. CLT was generally introduced into primary education with a view to family remigration. This objective was also clearly expressed in Directive 77/486 of the European Community, on July 25, 1977. The directive focused on the education of the children of 'migrant workers' with the aim 'principally to facilitate their possible reintegration into the Member State of origin.' As is clear from this formulation, the directive excluded all IM children originating from non-EU countries, although these children formed a large part of IM children in European primary schools. At that time, Sweden was not a member of the European Community, and CLT policies for IM children in Sweden were not directed towards remigration but modeled according to bilingual education policies for the large minority of Finnish-speaking children in Sweden.

During the 1970s, the above argumentation for CLT was increasingly abandoned. Demographic developments showed no substantial signs of

Figure 1 Outline of the Multilingual Cities Project.

remigrating families. Instead, a process of family reunion and minorization came about in the host countries. This development resulted in a conceptual shift, and CLT became primarily aimed at combating disadvantages. CLT had to bridge the gap between the home and the school environment, and to support school achievement in 'regular' subjects. Because such an approach tended to underestimate the intrinsic value of CLT, a number of countries began to emphasize the importance of CLT from a cultural, legal, or economic perspective:

- from a cultural perspective, CLT contributes to maintaining and advancing a pluriform society;
- from a legal perspective, CLT meets the internationally recognized right to language transmission and language maintenance, and acknowledges the fact that many IM groups consider their own language as a core value of cultural identity in a context of migration and minorization;
- from an economic perspective, CLT leads to an important pool of profitable knowledge in societies which are increasingly internationally oriented.

The historical development of arguments for CLT in terms of remigration, combating deficiencies, and multicultural policy is evident in some German states, in particular North Rhine-Westphalia and Hamburg. In most other countries in our study, cultural policy is tied in with the mainstream language to such an extent that CLT is tolerated only in the margins. Cultural motives have played a rather important role in Sweden. It should, however, be noted that multicultural arguments for CLT have not led to an educational policy in which the status of IM languages has been substantially advanced in any of the countries involved in our study.

Derived from Extra and Yağmur (2004), we give a crossnational overview of nine parameters of CLT in primary and secondary education that were taken into account in each of the six countries involved. CLT for primary school children came to an abrupt nationwide end in the Netherlands in 2004 as being 'in contradiction with integration,' and the information presented is therefore in retrospect.

Target Groups

The target groups for CLT in primary schools are commonly IM children, defined as such in a narrow or broad sense. Narrow definitions commonly relate to the range of languages taught and/or to children's proficiency in these languages. The most restrictive set of languages is taught in Spain, i.e., Arabic and Portuguese only, for Moroccan and Portuguese (-speaking) children respectively. A wide range of languages is taught in Sweden and Germany. The Netherlands, Belgium, and France take/took an intermediate position. Sweden and France demand from the target groups an active use of the languages at home and a basic proficiency in these languages. Special target groups in Sweden are adopted children; in Germany, ethnic German children from abroad; and in France, speakers of recognized RM languages. Sweden has the most explicit policy for access to CLT in terms of 'home language' (nowadays, back to 'mother tongue') instead of socio-economic status. The target groups for CLT in secondary schools are commonly those who participated in CLT in primary schools. *De jure*, all pupils are allowed CLT in the Netherlands, independent of ethnolinguistic background; *de facto,* most commonly, a subset of IM pupils takes part. CLT for secondary school pupils is almost nonexistent in Belgium, and limited to Arabic and Portuguese in a few secondary schools in Spain.

Arguments

The arguments for CLT are formulated in terms of a struggle against deficits and/or in terms of multicultural policy. Whereas the former type of argument predominates in primary education, the latter type predominates in secondary education. The vague concept of 'integration' utilized in all countries under discussion may relate to any of these arguments. Deficit arguments may be phrased in terms of bridging the home–school gap, promoting mainstream language learning, promoting school success in other ('regular') subjects, preventing educational failure, or overcoming marginalization. Multicultural arguments may be phrased in terms of promoting cultural identity and self-esteem, promoting cultural pluralism, promoting multilingualism in a multicultural and globalizing society, and avoiding ethnic prejudice. Whereas in the Netherlands and Belgium deficit arguments dominate(d), multicultural arguments tend(ed) to play a greater role in the other countries. Deficit arguments for CLT are almost absent in secondary schools, and multicultural arguments are commonly favored in all countries.

Objectives

The objectives of CLT in primary schools are rarely specified in terms of language skills to be acquired. The vague concept of 'active bilingualism' has been a common objective in Sweden, whereas in Germany and Spain, reference is made to the development of oral and written language skills, language awareness, and (inter)cultural skills. In none of these cases have more particular specifications been introduced. In

contrast, the objectives of CLT in secondary schools are commonly specified in terms of particular oral and written skills to be reached at intermediate stages and/or at the end of secondary schooling.

Evaluation

The evaluation of achievement through CLT may take place informally and/or formally. Informal evaluation takes place by means of subjective oral and/or written teachers' impressions or comments, meant for parents at regular intervals, e.g., once per semester or year. Formal evaluation takes place using more or less objective language proficiency measurement and language proficiency report figures, e.g., once per semester or year. Informal evaluation may occur in lower grades of primary schooling, formal evaluation in higher grades (e.g., in Sweden). In most countries, however, no report figures for CLT are provided throughout the primary school curriculum, and report figures for 'language' commonly refer implicitly to proficiency in the mainstream language. If CLT report figures are given (e.g., in France), such figures commonly do not have the same status as report figures for other subjects. The evaluation of achievement through CLT in secondary schools takes place formally through assessment instruments and examinations. Here, report figures may have a regular or a peripheral status. The former holds in particular for Sweden, Germany, and the Netherlands.

Minimal Enrolment

Minimal enrolment requirements for CLT may be specified at the level of the class, the school, or even the municipality at large. The latter is common practice only in Sweden, and the minimal enrolment requirement for children from different classes/schools in Sweden is five (2003/2004). Secondary schools in Sweden may also opt for CLT if at least five pupils enroll; four pupils are required in the Netherlands. All other countries are more reluctant, with minimal requirements for primary school pupils ranging between 10 and 20 (Germany, Belgium, France), or without any specification (the Netherlands and Spain). In the latter case, enrolment restrictions are commonly based on budget constraints.

Curricular Status

In all countries, CLT at primary schools takes place on a voluntary and optional basis, provided at the request of parents. Instruction may take place within or outside regular school hours. The latter is most common in Sweden, Belgium, and France. Germany, the Netherlands (until 2004), and Spain allow(ed) for two models of instruction, either within or outside regular school hours, depending on the type of language (in Germany), the type of goal (auxiliary or intrinsic in the Netherlands), and the type of organization (in integrated or parallel classes in Spain). The number of CLT hours ranges from 1 to 5 hours. If CLT takes place at secondary schools, it is considered a regular and optional subject within school hours in all countries under consideration.

Funding

The funding of CLT may depend on national, regional, or local educational authorities in the country/municipality of residence and/or on the consulates/embassies of the countries of origin. In the latter case, consulates or embassies commonly recruit and provide the teachers, and they are also responsible for teacher (in-service) training. Funding through the country and/or municipality of residence takes/took place in Sweden and the Netherlands. Funding through the consulates/embassies of the countries of origin takes place in Belgium and Spain. A mixed type of funding occurs in Germany and in France. In Germany, the source of funding is dependent on particular languages or organizational models for CLT. In France, source countries fund CLT in primary schools, whereas the French ministry of education funds CLT in secondary schools.

Teaching Materials

Teaching materials for CLT may originate from the countries of origin or of residence of the pupils. Funding from ministries, municipalities, and/or publishing houses occurs in Sweden, Germany, and the Netherlands, although limited resources are available. Source country funding for CLT occurs in Belgium and Spain. In France, source countries fund teaching materials in primary schools, whereas the French ministry of education funds teaching materials in secondary schools.

Teacher Qualifications

Teacher qualifications for CLT may depend on educational authorities in the countries of residence or of origin. National or statewide (in-service) teacher-training programs for CLT at primary and/or secondary schools exist in Sweden, Germany, and the Netherlands, although the appeal of these programs is limited, given the many uncertainties about CLT job perspectives. In Belgium and Spain, teacher qualifications depend on educational authorities in the countries of origin. France has a mixed system of responsibilities: source countries are responsible for teacher qualifications in primary schools, whereas

the French ministry of education is responsible for teacher qualifications in secondary schools.

The presented overview of given parameters shows that there are remarkable crossnational differences in the status of CLT. There are also considerable differences between primary and secondary education in the status of CLT. A comparison of all nine parameters makes clear that CLT has gained a higher status in secondary schools than in primary schools. In primary education, CLT is generally not part of the 'regular' or 'national' curriculum, and, therefore, becomes a negotiable entity in a complex and often opaque interplay between a variety of actors. Another remarkable difference is that, in some countries, CLT is funded by the consulates or embassies of the countries of origin. In these cases, the national government does not interfere in the organization of CLT, or in the requirements for and the selection and employment of teachers. A paradoxical consequence of this phenomenon is that the earmarking of CLT budgets is often safeguarded by the above-mentioned consulates or embassies. National, regional, or local governments often fail to earmark budgets, so that funds meant for CLT may be appropriated for other educational purposes.

The higher status of CLT in secondary education is largely due to the fact that instruction in one or more languages other than the national standard language is a traditional and regular component of the (optional) school curriculum, whereas primary education is mainly determined by a monolingual *habitus* (Gogolin, 1994). Within secondary education, however, CLT must compete with 'foreign' languages that have a higher status or a longer tradition. It should further be noted that some countries provide instruction and/or exams in nonstandard language varieties. In France, for instance, pupils can take part in examinations in several varieties of Arabic and several Berber languages (Tilmatine, 1997); Sweden offers Kurmanji-Kurdish as an alternative to Turkish. From mid-2004 on, the EU has been expanded with the inclusion of the national languages of 10 new EU countries. This leads to the paradoxical situation that the national languages of, for example, the three Baltic states are supported by more positive action ('celebrating linguistic diversity') in multilingual Europe than IM languages such as Turkish, spoken by many more people across Europe.

CLT may be part of a largely centralized or decentralized educational policy. In the Netherlands, national responsibilities and educational funds are gradually being transferred to the municipal level, and even to individual schools. In France, government policy is strongly centrally controlled. Germany has devolved most governmental responsibilities to the federal states, with all their differences. Sweden grants far-reaching autonomy to municipal councils in dealing with educational tasks and funding. In general, comparative crossnational references to experiences with CLT in the various EU member states are rare, or they focus on particular language groups. With a view to the demographic development of European nation-states into multicultural societies, and the similarities in CLT issues, more comparative crossnational research would be highly desirable.

Beyond Bilingualism: Dealing with Multilingualism at School

In Europe, language policy has largely been considered a domain which should be developed within the national boundaries of the different EU nation-states. Proposals for an overarching EU language policy were laboriously achieved and are noncommittal in character (Coulmas, 1991; *see also* **Language Education Policy in Europe** and **Language Policies: Policies on Language in Europe**). The most important declarations, recommendations, or directives on language policy, each of which concepts carries a different charge in the EU jargon, concern the recognition of the status of (in the order mentioned)

- national EU languages;
- 'indigenous' or RM languages;
- 'nonterritorial' or IM languages.

On numerous occasions, the EU ministers of education declared that EU citizens' knowledge of languages should be promoted (Baetens Beardsmore, 1993). Each EU member state should promote pupils' proficiency in at least two 'foreign' languages, and at least one of these languages should be the official language of an EU state. Promoting knowledge of RM and/or IM languages was left out of consideration in these ministerial statements. The European Parliament, however, accepted various resolutions which recommended the protection and promotion of RM languages and which led to the foundation of the European Bureau for Lesser Used Languages in 1982. Another result of the European Parliament resolutions was the foundation of the European Mercator Network, aimed at promoting research into the status and use of RM languages. In March 1998, the European Charter for Regional or Minority Languages came into operation. The charter is aimed at the protection and promotion of RM languages, and it functions as an international instrument for the comparison of legal measures and other facilities of the EU member states in this policy domain (Craith, 2003).

Bilingual education in national majority languages and regional minority languages has been an area of

interest and research for a long time (Baker, 2001). More recently, local and global perspectives are taken into consideration that go beyond bilingualism and focus on multilingualism and multilingual education. Apart from national majority and regional minority languages, the focus is commonly on the learning and teaching of English as a third language, and in this way on promoting trilingualism from an early age (Cenoz and Genesee, 1998; Cenoz and Jessner, 2000; Beetsma, 2002, Ytsma and Hoffmann, 2003).

As yet, no affirmative initiatives have been taken in the European policy domain of IM languages. It is remarkable that the teaching of RM languages is generally advocated for reasons of cultural diversity as a matter of course, whereas this is rarely a major argument in favor of teaching IM languages. The 1977 guideline of the Council of European Communities on education for IM children (Directive 77/486, dated July 25, 1977) is now outdated. It needs to be put in a new and increasingly multicultural context; it needs to be extended to pupils originating from non-EU countries; and it needs to be given greater binding force in the EU member states.

There is a great need for educational policies in Europe that take new realities of multilingualism into account. Processes of internationalization and globalization have brought European nation-states to the world, but they have also brought the world to European nation-states. This bipolar pattern of change has led to both convergence and divergence of multilingualism across Europe. On the one hand, English is on the rise as the lingua franca for international communication across the borders of European nation-states at the cost of all other national languages of Europe, including French. In spite of many objections against the hegemony of English (Phillipson, 2003), this process of convergence will be enhanced by the extension of the EU in an eastward direction. Within the borders of European nation-states, however, there is an increasing divergence of home languages due to large-scale processes of migration and intergenerational minorization.

The call for differentiation of the monolingual *habitus* of primary schools across Europe originates not only bottom up from IM parents or organizations, but also top down from supranational institutions which emphasize the increasing need for European citizens with a transnational and multicultural affinity and identity. Multilingual competencies are considered prerequisites for such an affinity and identity. Both the European Commission and the Council of Europe have published many policy documents in which language diversity is cherished as a key element of the multicultural identity of Europe – now and in the future. This language diversity is considered to be a prerequisite rather than an obstacle for a united European space in which all citizens are equal (not the same) and enjoy equal rights (Council of Europe, 2000). The maintenance of language diversity and the promotion of language learning and multilingualism are seen as essential elements for the improvement of communication and for the reduction of intercultural misunderstanding.

The European Commission (1995) opted in a so-called White Book for trilingualism as a policy goal for all European citizens. Apart from the 'mother tongue,' each citizen should learn at least two 'community languages.' In fact, the concept of 'mother tongue' referred to the national languages of European nation-states and ignored the fact that mother tongue and national language do not coincide for many inhabitants of Europe. At the same time, the concept of 'community languages' referred to the national languages of two other EU member-states. In later European Commission documents, reference was made to one foreign language with high international prestige (English was deliberately not referred to) and one so-called neighboring language. The latter concept related commonly to neighboring countries, never to next-door neighbors.

In a follow-up to the first European Year of Languages, proclaimed in 2001, the heads of state and government of all EU member states gathered in 2002 in Barcelona and called upon the European Commission to take further action to promote multilingualism across Europe, in particular by the learning and teaching of at least two foreign languages from a very young age (Nikolov and Curtain, 2000). The final Action Plan 2004–2006, published by the European Commission (2003), may ultimately lead to an inclusive approach in which IM languages are no longer denied access to Europe's celebration of language diversity. In particular, the plea for the learning of three languages by all EU citizens, the plea for an early start to such learning experiences, and the plea for offering a wide range of languages to choose from open the door to such an inclusive approach. Although this may sound paradoxical, such an approach can also be advanced by accepting the role of English as a lingua franca for intercultural communication across Europe.

Against this background, the following principles are suggested for the enhancement of multilingualism at the primary school level:

1. In the primary school curriculum, three languages are introduced for all children:
   - the standard language of the particular nation-state as a major school subject and the major language of communication for the teaching of other school subjects;

- English as a lingua franca for international communication;
- an additional third language chosen from a variable and varied set of priority languages at the national, regional, and/or local levels of the multicultural society.

2. The teaching of these languages is part of the regular school curriculum and subject to educational inspection.
3. Regular primary school reports provide, formally or informally, information on the children's proficiency in each of these languages.
4. National working programs are established for the priority languages referred to under (1) in order to develop curricula, teaching methods, and teacher training programs.
5. Part of these priority languages may be taught at specialized language schools.

This set of principles is aimed at reconciling bottom-up and top-down pleas in Europe for multilingualism, and is inspired by large-scale and enduring experiences with the learning and teaching of English (as L1 or L2) and one language other than English (LOTE) for all children in the state of Victoria, Australia (see Extra and Yağmur, 2004). When each of the above-mentioned languages should be introduced in the curriculum, and whether or when they should be subject or medium of instruction, should be spelled out depending on particular national, regional, or local contexts. Derived from an overarching conceptual and longitudinal framework, priority languages could be specified in terms of both RM and IM languages for the development of curricula, teaching methods, and teacher-training programs. Moreover, the increasing internationalization of pupil populations in European schools requires that a language policy be introduced for **all** schoolchildren in which the traditional dichotomy between foreign language instruction for indigenous majority pupils and home language instruction for IM pupils is put aside. Given the experiences abroad (e.g., the Victorian School of Languages in Melbourne, Australia), language schools could become centers of expertise where a variety of languages are taught, in particular if the number of children requesting instruction in these languages is low and/or spread over many schools. In line with the proposed principles for primary schooling, similar ideas could be worked out for secondary schools where learning more than one language is already an established practice. The above-mentioned principles would recognize multilingualism in an increasingly multicultural environment as an asset for all children and for society at large. The EU, the Council of Europe, and UNESCO could function as leading transnational agencies in promoting such concepts. The UNESCO Universal Declaration of Cultural Diversity is in line with the inclusive views expressed here, in particular in its plea to encourage language diversity, to respect the mother tongue at all levels of education, and to foster the learning of several languages from the youngest age.

Recent progress in technology-enhanced language learning has been concentrated in two broad areas: Multimedia and Information Technologies (IT, also commonly known as ICT, Information and Communication Technologies). Information Technologies came about as the result of advances in computer networking, which fundamentally changed the flow of information at every level of our society. IT became critical in order to manage the vast amount of information. Arising from the continuous developments in computer processing power and increasing storage capacities, digitization of different types of media

Recent progress in technology-enhanced language learning has been concentrated in two broad areas: Multimedia and Information Technologies (IT, also commonly known as ICT, Information and Communication Technologies). Information Technologies came about as the result of advances in computer networking, which fundamentally changed the flow of information at every level of our society. IT became critical in order to manage the vast amount of information. Arising from the continuous developments in computer processing power and increasing storage capacities, digitization of different types of media

has proliferated, resulting in vast archives of text, audio, graphics, photographs, and video stored in digital form. Computers became powerful enough to integrate these media in the digital form and to handle them seamlessly in a user-friendly manner. Audiocassettes and videotapes are rapidly giving way to digital formats, including CDs, DVDs, and digital media computer servers. More digital cameras are being sold than traditional film-based cameras. The majority of consumer-grade video camcorders now use the digital formats. Language learning venues are also going through a transition. Language students of the 1960s and 1970s diligently visited the audio language laboratory, for class meetings and for homework and self-study. This picture changed and broadened with the advent of the microcomputer and the Internet. Audiotape language laboratories were replaced by media centers that delivered a wide range of audio, video, and multimedia computer resources. The expansion of language learning spaces continues as students use their own computers for their learning without needing to go to computer laboratories. This shift in the learning environment is a direct result of the diminishing size of computer hardware, ubiquitous connectivity to the Internet, and the ever-increasing availability of wireless network connections.

Language teachers have always exploited any technology that would allow them to bring the language and culture alive for their students. Currently, technology serves a variety of functions: a multimedia information and reference channel for exploring the culture and language; a tutor that provides information, practice, help, and instant feedback in a self-paced environment; an assessment tool; a productivity-enhancing means of composing, revising, and disseminating written production; and a way for teachers and learners to communicate and work collaboratively. Older tried-and-true technologies are never instantly replaced by newer ones, but rather they coexist for an extended period of time – not only for reasons of software availability, but because they genuinely work better for the instructional need or for the instructor's approach to teaching. The next section focuses on the major developments and advances that have emerged during the past 10 years and that have influenced the use of technology in language learning and teaching.

Key Developments in the Last Decade

Most successful technology-driven developments in education have paralleled general trends in the corporate and the consumer market. The language profession is no different from other academic disciplines in exploiting the 'generic' tools that have emerged for business and consumers as a result of the Internet, including World Wide Web pages, computer conferencing, and training or learning management systems. In fact, when compared with Computer-Assisted Language Learning (CALL) applications of the 1980s and early 1990s, these generic tools have been embraced with much more enthusiasm than we have ever witnessed with any technology of the past. Whereas the period from 1984 to 1994 in CALL development was characterized by custom programs anchored to local workstations equipped with multimedia peripherals (random-access audio devices, videodisc players, CD drives), many contemporary CALL ventures are moving toward a web-based model of anytime, any-place connectivity to digital resources of all kinds – text, graphics, sound, photos, and video – and more online human-to-human interaction, both synchronous (in real time) and asynchronous (at delayed intervals).

A shift similar to the shift from custom programs to more generic tools is seen in the learning environment. Dedicated language laboratories have been replaced by more general-purpose computer laboratories. Technological advances in hardware, such as higher processing speed of computer chips and increasing capacities of storage devices, have made this shift possible. As the wireless networks become widespread and individuals carry their own computers, many of the learning activities that happened in room-based computer laboratories will inevitably shift to personal portable devices of all kinds, including handheld computers and multipurpose cellular phones.

Exponential Growth of the Internet and the World Wide Web

Without any doubt, the technological advance that has had the greatest impact on the teaching and learning of foreign languages is the exponential growth of the Internet and the World Wide Web. Although the Internet and the Web are frequently used as interchangeable terms, a stricter distinction can be made. The Internet refers to the network of the physical connections and protocols that link computers to one another (an invention attributed to the U.S. government), as distinguished from the Web, which is the Internet-based phenomenon that came into being in 1990, when Tim Berners-Lee created the World Wide Web at a lab in Switzerland by establishing the notion of the Universal Resource Locator (URL), which together with hypertext markup language, forms the basis of current resources accessed by browser applications, such as Internet Explorer. The Internet has spread to many parts of the world,

saturating developed nations and increasingly penetrating countries traditionally at the margins of technological growth. This growth can mean significant access to native speakers and native language and cultures for students in a wide range of target languages except those spoken primarily in areas where speakers have neither a tradition of written language nor a culture of computer usage.

English dominated the Web at the beginning and currently accounts for approximately one-third of the online language population. However, if trends continue as they have in the past several years, the online language populations on the Internet will continue to shift toward a better language balance as Internet technology pervades all regions of the world, especially Africa, Asia, the Middle East, and Latin America. Due to the growth of the Web, personal computer operating systems have become much friendlier to a wider range of languages including nonalphabetical languages and right-to-left languages. (See the section below on Unicode for character handling.)

The Web offers a wealth of authentic linguistic and cultural artifacts usable at many moments in instruction, both during and outside of class, and at all levels. The acceptance of the Web into the foreign language profession was smooth and swift because it was strongly content-driven and no hardware changes were necessary. In fact, no past instructional technology or application has resonated so completely with our profession and been embraced in so short a time as has the Web, not only because of content and ease of use, but because of the potential for building varied communities of learners through good connectivity.

Computer-Mediated Communication

In the early 1990s, the few instructional language projects using the Internet were limited primarily to asynchronous (delayed response) e-mail exchanges and synchronous (real-time) class discussions on local area networks (LANs). During the past decade, the Internet blossomed as a mature communication medium – one even better suited to the instructional goals of language learning. Thus, from the first electronic communication experiments has emerged a new multifaceted domain known as computer-mediated communication (CMC), comprising both synchronous and asynchronous communication modes. In addition to traditional e-mail and LAN-based class discussion, the possibilities now include Instant Relay Chat (IRC) text messaging, graphical chat with sound, threaded discussion, MOOs (Multiple user domain-Object Oriented, environments based on interactive online gaming software), and Internet-based audio and video teleconferencing systems, all of which make possible authentic language learning experiences and radically different learning communities in which language learners are connected to native speakers of their target language.

Since many forms of CMC require text in the electronic form, learners must learn to type in the target language. Though typing in alphabetical languages is a relatively simple task, the issues of typing in nonalphabetical languages are more complex. Teaching students how to use the input systems for languages such as Chinese and Japanese efficiently enough for them to communicate in a spontaneous fashion constitutes a significant inhibition to online communication in these languages. In fact, the instructional use of word processing and the Internet has an impact on the instruction of the orthography by redefining what constitutes the writing ability. In other words, students may not have to be able to write a large number of characters by hand.

Synchronous online exchanges have recently been the object of a great deal of research – analyzing the nature of the language/discourse in CMC, the importance of task in language production, and the nature of the social or intercultural interactions as they occur in this medium. A number of notable experiments in CMC involving foreign language classes in the United States and English learners in Europe have revealed the challenges and benefits of connecting language students with native speakers of the target language. Pennsylvania State's Telecollaboration Project, MIT's Cultura Project, and Vassar's Moossiggang all demonstrate that students are motivated by these collaborative exchanges and engage in productive learning activities that promote authentic use of the language, using the language for authentic communication rather than as the object of study. Despite the reported successes of such projects, significant problems persist: crosscultural misunderstandings, unequal access to technology, mismatches of school calendars, differences in student motivation and rewards leading to disparate levels of commitment, and sound methods of assessment.

Course Management Systems

Course Management Systems (CMSs), also commonly known as Virtual Learning Environments and Learning Managements Systems, have made a major impact on all disciplines at postsecondary institutions. These e-learning systems are designed to provide a flexible, multifaceted environment for creating online course materials. They have been used to supplement face-to-face learning as well as to deliver classes that are conducted completely online. Among

these electronic learning environments, WebCT and Blackboard dominate the market in the United States, Europe, Asia, Australia, and other parts of the world. These 'e-learning' systems combine various modalities under one umbrella: dissemination of course information and content (multimedia materials, links to websites, quizzing), grade book, threaded discussion, and chat – all with password-protected access. Many language teachers who were never attracted to computer technology in the past have found such systems useful because they allow students to engage in meaningful language learning activities outside of class, working either individually or in groups. In addition, they make use of CMSs to manage routine course-administration tasks.

Distance/Online Learning

Much of online learning takes place as an aspect of hybrid environments that combine face-to-face classroom instruction and activities with online exploration and activities. At some institutions, a significant number of face-to-face classroom meetings have been replaced by online exercises and assignments as a cost-saving measure. Other initiatives have a more positive spin toward exploiting online technology. One interesting example of an online language program to supplement regular instruction and to develop and research the best practices for distance learning is Hilde's Witchy World (*Hildes Hexenwelt)*, developed by Uschi Felix (Monash University). Hilde's Witchy World is an experimental distance learning resource for second-year German that is based on a constructivist approach to language learning.

Although technology-enhanced distance language learning as an alternative to face-to-face classroom instruction has been a long-established tradition in Europe, this has not been the case in the United States until very recently. In the United States, schools and universities have begun to look toward joint distance education arrangements, primarily for the less commonly taught languages that cannot be offered economically at a single institution, especially for advanced levels. Through recent projects in Swahili, Yoruba, Arabic, and Hindi, practitioners are beginning to discover how best to deliver online instruction in these languages to students from several institutions. Typically, distance language learning courses utilize a range of technologies to deliver instruction and connect learners and instructors, including Web-based multimedia materials, real-time chat, threaded discussion, and videoconferencing (technology that allows participants at two or more sites to see and hear one another), along with more traditional off-line materials, such as textbooks and audio and video on cassette or disc. Instruction is usually offered synchronously, which helps foster a sense of learner community and provides interactive communicative experiences among learners.

Videoconferencing or teleconferencing itself has changed a great deal in recent years. Once restricted to expensive satellites and dishes, video teleconferencing with multisite audio and video communication has moved to the domain of the Internet. Early basic Internet conferencing applications, such as CU-SeeMe and Netmeeting, have been expanded and improved to provide audio and video communication integrated with other shared media- and computer-based programs. With such technology, it has become possible to offer distance language instruction with a highly interactive face-to-face feel. As with other media-intensive Internet applications, 'bandwidth' (high-speed, high-capacity network connections) is an important and limiting factor and current videoconferencing systems tend to experience periodic problems of audio and video dropouts when Internet traffic is heavy. However, as the bandwidth expands, the capability of teleconferencing technology will improve and become a more viable conduit for language learning.

Even in the traditional arena of language laboratories, there has been a transformation from analog systems to online digital environments. Currently, the market is dominated by language laboratory software run on LAN-based systems as well as browser-based virtual classroom systems for real-time teacher-led learning environments for distance education applications.

Concordancing Programs and Corpora

The instructional use of concordancing programs and corpora for language learning has continued to represent a noteworthy area for development. Originally a discipline largely unrelated to language instruction, corpus linguistics has increasingly been linked to second and foreign language research, yielding a new area of inquiry to inform language teaching and learning practice. Computer software tools – concordance programs – for searching large collections or corpora of natural language (from print or spoken sources) can be used both for autonomous learning activities and for diagnostic and research ends. For example, corpora consisting of texts written by learners of English as a Foreign Language have been useful in systematically identifying errors consistently made by speakers of given languages, allowing teachers to design curricular strategies that specifically address known problems. In other languages, the corpora of authentic texts are being used to allow

students to explore texts to draw conclusions about lexical usage and structural patterns.

L2 Phonology and Speech Recognition

Pronunciation training is an area where technology has been used effectively. When a computer makes a digital recording of a learner's utterances, software analyzes the voice and gives visual feedback in the form of spectrograms and pitch contours. This type of technology was originally developed for speech pathology and phonology research. Computers have become powerful enough to process the sound in real time as the student's voice is recorded.

Speech recognition is another type of speech technology that has been in practice as a dictation tool for professional writers and translators and for persons with disabilities. Such applications are often speaker-dependent systems designed for native speakers. They require 'training' the system to understand accurately the voices of particular individuals. Once trained, the system works remarkably well, converting continuous speech into written text. On the other hand, speech recognition systems for language learners do not require training and thus are speaker-independent. This type of system needs to perform automatic speech recognition to determine the acceptability of voice input. There are some pronunciation training programs available commercially for vocabulary, but the recognition of continuous speech produced by language learners remains difficult, and reviews of those programs by language experts are still mixed. Once this technology evolves further, speech recognition systems have the potential to provide objective feedback for acceptable pronunciation.

Unicode

As computer use spread globally, devising a system of uniform character representation emerged as a pressing issue. Unicode constitutes a significant development in managing characters when multiple languages need to be supported on a computer. Unicode originated in the 1980s at Xerox as a part of a project to develop a multilingual word processor. As described on their website (http://www.unicode.org), the objective of Unicode is to provide a unique number for every character of every language, no matter what the computer platform or program. Recent versions of common operating systems support Unicode. In the character set menu of popular Web browsers, Unicode is available under the names UTF-8 and UTF-16. Once Unicode is widely adopted and standard Unicode fonts become available, Unicode will vastly improve and simplify multilingual computing.

Issues and Concerns

There is always great disparity between predictions for technology in education and the reality of its implementation, between technological advances and the successful use of technology for language learning and teaching, and between language acquisition theory and classroom practice. Added to these perennial problems, CALL developers now also grapple with a number of thorny issues that complicate the implementation of Information and Communication Technologies in language learning.

Coping with Change

The trend in much of instructional technology for language learning and teaching is to make use of existing networks and generalized tool software – exploiting the power of sophisticated environments, backed by corporate resources that ensure continued support for their products. Thus, the emergence of course management and e-learning systems, Internet-based teleconferencing systems, and multimedia presentation and development tools (used by teachers and students alike) has stimulated a move away from custom-programmed applications that characterized CALL in the 1980s and 1990s. The popularity of the Web, with its wealth of authentic materials and its promise of any-time, any-place availability, has had a profound effect in overshadowing custom stand-alone applications Most new development is aimed at Web delivery and e-learning, rather than traditional distribution by CD-ROM or other physical media delivered in a traditional bricks-and-mortar institutional setting. As a result, many complex and sophisticated projects do not attract the necessary resources to migrate programs from old platforms and systems to new ones, and many developers are undergoing a painful process of reinventing old CALL wheels in more undeveloped and restrictive browser-based delivery environments. Web-based CALL templates produced by academic or government groups (such as the Hot Potatoes suite of templates developed by Stewart Arneil and Martin Holmes at the University of Victoria or the MALTED system developed by Paul Bangs and supported by Spain's Ministry of Education) expend great effort and resources to remain viable as platforms and browsers change and evolve.

The Downside of the Web

The Web has proven to be both a blessing and a curse to language teachers and learners. The wealth of authentic material from and about world cultures available via the Web can constitute information overload

for language learners, causing them to struggle to keep their bearings through endless jumps through hyperspace as they attempt to discern good information from bad. There is a tendency to trust the Web as a source of true and accurate information, and often students will naïvely read and quote information as gospel, when, in fact, it is of questionable accuracy. Teachers' efforts to create flexible, up-to-the-minute instructional content on the Web too often fall into neglect, resulting in permanently out-of-date relics, with links that point to pages that have disappeared completely.

Software Development Standards

Because of the open nature of the Web and the resources required for the development of sophisticated software tools and courseware, accessibility, intellectual property rights, reusability, and interoperability have arisen as meaningful issues for developers and educators. In the United States, major ventures have been developing standards for specifying and managing 'learning objects,' defined as identifiable individual elements of instructional materials, in the interest of sharing content and ensuring the continued viability of tools and content as changes in platforms occur. Two major initiatives in the development of learning object standards, IMS (Instructional Management System) and SCORM (Sharable Content Object Reference Model), have champions among some software and course management system developers, but objectively they have had little impact on most instructional software for languages developed by either local academic projects or publishers. Major course management systems, including Blackboard and WebCT, claim conformance to IMS and SCORM standards so that learning objects can be moved to different or upgraded systems, but, in reality, the definition of conformance varies considerably from product to product.

Practice Linked to SLA Theory and Research

In the next decade, greater effort will doubtless be made to link Second Language Acquisition (SLA) theory and research to practice. Technology figures into many solutions to issues raised by current SLA research, including motivation, learner styles and preferences, awareness, authenticity, interaction, feedback, and the social and cultural contexts of language learning. Unfortunately, the field of CALL has not traditionally been the target of rigorous research, partly due to the ever-changing nature of technology. Taken at face value, technology offers many benefits: access to enhanced content, multiple modalities for interaction and communication, opportunities for active learning, potential for feedback and tracking of learner progress, support for diverse learning styles, and increased time spent in productive language learning activities. However, the future of sophisticated, effective applications of technology to language learning depends on applying the theoretical research framework of SLA to CALL development. The research can inform principled development of software and activities with regard to issues of design, effectiveness, outcomes, and learner variables, answering questions such as what forms should feedback take and under what circumstances, what effect does task type have on language production, how do outcomes differ in program-controlled vs. learner-controlled learning systems, and so forth. Much of the research to date, for better or worse, compares the use of CALL with face-to-face instruction. As the domains of SLA theory and CALL become more intimately linked, there will be a greater emphasis on researching technology-based applications in their own right, rather than as alternatives to standard classroom practices.

Furthermore, research on SLA can be conducted in computer-based environments, which provide controlled environments for tracking or recording research data. Many insights about the process of language learning and about language learners will be gained by conducting research using technologies that can completely and accurately capture learner interactions and moves for thorough analysis.

Technological Standards

Few technologies have become standardized worldwide, so we have long been obliged to deal with differences in the way things work in different parts of the world through transformers, plug converters, multistandard devices, and the like.

Problems with different world television broadcast standards, something we hoped would disappear with digital video technologies, have not only persisted, but will certainly not be resolved for some time to come. In the realm of DVDs, the three major broadcast standards we grappled with for playback of video from foreign countries – PAL, SECAM, and NTSC – have been reduced to two – PAL and NTSC – but we now suffer from the additional complication of six regional codes, added to the disc to prevent playback of a DVD produced in one region of the world from playing on a device produced in another region of the world, purportedly to protect the rights of the original producers. Moreover, DVD technology continues to evolve toward different compression standards and new hardware.

Computer-based digital video has fared no better, with a number of competing proprietary standards

for encoding (storing and compressing) video, including MPEG, QuickTime, Real, and AVI, each with its own playback requirements on the local workstation. Nevertheless, the power of video as a teaching medium drives us to adjust to all the technological challenges in the interest of bringing lively, motivating examples of language and culture to our students.

The profession is still fairly far from making a complete transition from established analog and digital formats, primarily VHS cassettes and DVD, to online digital video. The enormous bandwidth required for reliable, high-quality playback of digital video has impeded progress toward widespread delivery of centralized server-based instructional video. Reliably transporting data-intensive video streams through many common computer conduits – busy shared networks, wireless connections, and phone modems – remains a challenge, but one that will be resolved as communication technologies evolve.

Teacher Preparation and the Changing Role of the Teacher

It is often claimed that in new student-centered, technology-rich models of language instruction, the role of the teacher changes from the primary deliverer of instruction at the front of the class to that of an instructional designer and mentor. However, the majority of today's language teachers continue to be the 'sage on the stage' rather than the 'guide on side' envisioned by educational reformers. One of the greatest barriers to this transition is in the lack of effective teacher preparation in using technology for language learning. In order to make full use of technology tools, both preservice and in-service language professionals need to receive appropriate training. It is essential that language professionals not only become familiar with available technology, but feel at ease using various tools. A number of projects, large and small, are trying to define the necessary components and levels of such training (e.g., National Educational Technology Standards (NETS), Information and Communication Technology for Language Teachers (ICT4LT)). Based on the results of these projects, many institutions of higher education offer courses on educational technology or technology modules as a part of language teaching methods courses.

Old Wine in New Skins

Another issue that relates to the lack of teacher preparation in technology is the issue of effecting real changes in the way teachers teach and students learn with technology. When confronted with new technologies, the first impulse has been to transfer old media (especially print) onto computers without imagining new models of presentation and interaction. If one eliminates the posting of print materials and delivery of digital video and audio as an alternative to cassette and disc formats, there is much less innovative use of technology in language teaching and learning than we would like.

As noted above, the recognized need for language teachers to be knowledgeable about technology and CALL applications has resulted in courses and workshops on CALL and teaching with technology for both preservice and in-service teachers. However, despite heightened awareness of technology and the opportunities for change in pedagogical models for language learning, such change is slowed by attitudes, beliefs, and ingrained practices. Thus, we have many isolated experiments with radical technology-driven changes in language teaching and learning, but little movement in the overall profession toward unified methods of language learning with technology.

Importance of Infrastructure

The patterns of use of language learning technology are dictated to a great extent by institutional infrastructure. The ideal technology infrastructure features a variety of venues equipped with up-to-date technology to meet the various needs of students and teachers in the complex process of language instruction: presentation classrooms, computer classrooms, and media centers with stations for individual work and small group rooms for collaborative activities. These spaces are linked to high-speed networks, both wired and wireless, for access to the Internet and they provide access to a panoply of software and digital resources. Support personnel are available to provide assistance to users and to coordinate and maintain resources. To complement these institutional models, learners and teachers increasingly count on personal technologies and connections that enable them to tap into the virtual resources available within traditional educational institutions.

Professional Factors That Affect Technology and Language Learning

General Trends in Language Education

The current use of language learning technology has been shaped by a number of significant trends in language education. The profession has become oriented toward a more holistic approach to language education that moves beyond learning the forms of the language to attaining both language proficiency and developing crosscultural insights and strategies for effective communication with other people.

Performance-based assessment is favored over assessment of factual knowledge and discrete skills. Collaborative group work is valued as an effective learning strategy to provide authentic language experiences. The concept of students as lifelong learners influences us to broaden language curricula with an eye toward development of critical thinking skills in a multidisciplinary context. We have begun to favor student-directed, student-centered learning models over teacher-directed instruction and we are making greater efforts to accommodate different learner styles and strategies and to reach all language learning populations – learners with disabilities, adult learners, and learners in remote locations.

Multimedia and Information and Communication Technologies have an important role to play in all of these trends. Teachers have come to rely increasingly on the richness and depth of authentic multimedia materials for all levels of language learning to challenge students and help them cope with the language and culture that they will confront in the real world. Much of current software design reflects the trend away from the focus on development of discrete skills – reading writing, listening, speaking, culture, grammar, vocabulary – and information, toward an integrative or process approach that encompasses more natural experiences that support the development of multiple skills.

Standards for Foreign Language Education and Technology

Looking toward the new millennium, organizations set out to articulate general principles and measures for language education, including the use of new technologies. The most robust of these standards initiatives is the Common European Framework of Reference for Languages, an extensive reference that presents guidelines for the development of course materials (syllabi, curriculum, instructional materials, and assessment tools), describes what knowledge and skills learners must acquire to communicate in a language and function effectively in the cultural context of the target language, and defines levels of proficiency for language learners at all stages of learning. Specific references to technology are interwoven throughout the document and focus on exploiting new Information and Communication Technologies to promote 'plurilingualism and pluriculturalism,' enable pan-European links and exchanges, and support national and international structures to facilitate autonomous language learning and distance education. These references also focus on training teachers to be competent and confident users of technology for instruction. Though media types addressed in the Framework include a variety of text, video, and audio resources in a number of different formats, computers and computer skills predominate throughout the Framework for delivery of content in the classroom and laboratory, for individual self-instruction, and for conferencing that permits group activities.

In similar fashion, the American Council on the Teaching of Foreign Languages (ACTFL) produced their National Standards for Foreign Language Education, which identified general goals, standards, and progress indicators for language education as well as provided sample activities and learning scenarios. Predictably, the use of a variety of technologies, both traditional and computer-based, is supported in the Standards as a means of strengthening the linguistic skills needed to communicate effectively, interacting with peers and others in the target language, and developing knowledge and understanding of other cultures.

Professional Organizations and e-Journals

One measure of the professionalization of the field is the growing number of national and international organizations that are devoted to technologies and language learning, particularly CALL. These organizations promote the effective use of technology in language learning and serve as conduits for the exchange of expertise and information among professionals. They generally offer a variety of services to their members: conferences, workshops, special interest groups, journals, electronic discussion lists, and special print and electronic publications. The directory of these organizations includes IALLT (the International Association for Language Learning Technology), CALICO (the Computer-Assisted Language Instruction Consortium), EUROCALL (the European Association for Computer-Assisted Language Instruction), APACALL (Asia–Pacific Association for Computer-Assisted Language Learning), and PacCALL (Pacific Computer-Assisted Language Learning Association). These groups have attracted memberships that are broadly international, out of which have grown joint initiatives such as WorldCALL, a periodic worldwide CALL conference supported by many organizations, and FLEAT (Foreign Language Education and Technology), a periodic conference sponsored jointly by IALLT and the Japan Association for Language Education and Technology.

For reasons of economy as well as ease, breadth, and timeliness of dissemination, electronic journals have appeared as respected alternatives for peer-reviewed publication of scholarly work. The premier e-journal for CALL is *Language Learning and*

Technology, a refereed journal for second and foreign language educators that is delivered via the Web free of charge. Other journals offer electronic options (in addition to the printed version) to members and to institutions. For example, CALICO has journal articles from 1983 through 2000 available online, and electronic subscriber services provide access to *System*, a journal for educational technology and applied linguistics.

The Future

Predicting the future of language learning technology is a risky, even foolhardy, undertaking. Pronouncements about the success, failure, or future of any given technology tend to sound absurd 10 or 20 years later. However, based on the past lessons and current trends, some general assumptions about technology and language teaching and learning can be made. The transformation of media to digital forms is certain, as is the move toward greater portability of technology and ubiquitous wireless connectivity to the Internet. As Nicolas Negroponte, chairman of MIT's Media Lab, has said, "We're entering a period where we will be eating, wearing and breathing computers" (*Wired News*, 11 May 2004). But how long it will be before humans can have natural, open-ended conversations with computers or whether realistic virtual-reality language learning environments will ever emerge is anyone's guess. As new technologies emerge, language professionals, inspired by the appeal of the technology and by intuitions based on pedagogical experience, will examine and experiment with them, adopting those that prove fruitful for language learning. Under ideal conditions, the efficacy of adopted technologies will then be confirmed by testing and research.

Technical Translation and Technical Translators: Definitions

Technical texts can be defined somewhat broadly and refer to a range of subject fields including economics, law, politics, medicine, IT, and media. However, the most widely accepted definition, used in this article, classifies such texts as belonging to applied science, because technology is the application of science. Whereas science is about knowledge and study of natural phenomena, technique is about its application and its know-how. In other words, although science and technology are interdependent, scientific translation is primarily concerned with ideas and professions; technical translation concerns objects and trades, and transfers information about how things are produced and work. Broad areas of technology include mechanical engineering, hydraulics, electrical engineering, electronics and information technology. The spectacular development of technology in recent decades is characterized by two essential features: first, documents are produced exponentially, quickly outdated, and can be circulated globally instantly; second, the complexity of information is deepening into more subfields exclusive to experts. Some of these subfields grow into subject fields of their own. Information technology, because of its virtual basis, its huge growth, wide-reaching application, and commercial development, has thus become an area of its own. It is essentially concerned with transmitting data about data (*see* **Localization**). In traditional technology, such as mechanical engineering, data is transmitted about materials and equipment. Most technical translations transfer information about designing, manufacturing, using, and repairing products within an industrial context. Although such products are created according to general principles in science and technology, they are considered in very concrete, practical, and specific ways to satisfy the needs of the industry. Technical documents also are produced for immediate consumption and generally have short-term use, as technology evolves rapidly and as terminology can vary from place to place, even within one country. This implies that a technical translator must be familiar with basic scientific principles and general technology notions, and also aware of systems used in industry: measurement units, acronyms, symbols and abbreviations, names of commercial products, item description systems, templates and patterns, names, properties, and the use of different materials. Technical translators have to collaborate with experts and engineers both in the source and target languages. They also are cultural mediators, as they have to adapt information to a particular public, context, and market, for particular purposes.

Technical Translation: Past and Present

In many ways, the problem of disseminating scientific knowledge and technical information today is not very different from what it was in the worlds of antiquity, the Middle Ages, and the Renaissance. An international market using a lingua franca (Greek, Latin, English) develops before or in parallel with national markets, and involves mediation from and into vernacular languages, although in the past it often occurred from and into two lingua francas (mainly from Greek into Latin). Scientific writers remained largely anonymous in Europe until the Renaissance, as famous or established scientific figures, such as Euclid, collected the work of others. Their translators were working as anonymously as the authors of the original texts. Not many traces of the ancient Greeks' translation activities are left today. They are more visible in ancient Rome, where successful literary translators were recognized and praised for their work (Plautus, Terence), and professional translations were often done by Greek slaves, from Greek into Latin. The large empires of the ancient world (Egypt, Greece, Rome, China) seem to have dealt with translation in one or two language pairs. The establishment of the Islamic Arab Empire between the 7th and the 13th centuries promoted communication and exchanges with a range of cultures. "The Arabs are credited with initiating the first organized, large-scale translation activity in history" (Baker, 2001: 318). This activity was not confined to literary and religious documents. It extended to many areas, in particular mathematics, astronomy, alchemy, medicine, and chemistry, and a wide array of languages: from Sanskrit, Syriac, Greek, Aramaic, Persian, and other languages, into Arabic. In Europe, Renaissance scientific and technological developments are based on reappropriation of the knowledge of the antiquity through translation. In the 16th century, scientists, educated in a humanist and philological tradition, translated medical and scientific Greek manuscripts into Latin and sometimes into vernacular languages. "Thomas Linacre (1465–1542) Professor of Medicine at Oxford and Janus Cornarius (1500–1588) first Dean of Medicine at Jena scoured

European libraries for Greek medical and scientific manuscripts" (*see* **Translation: History**). Authors also started to write technical treatises in vernacular languages which were sometimes translated into Latin, such as the geographer Sebastian Münster's *Cosmography*, originally written in German in 1544, translated within the next 15 years into Latin, then French, English, Bohemian, and Italian. Power shifted from religious and humanist to scientific subjects, as technology grew and as international organizations developed from the 18th century onward. Language systems aimed at classifying elements of an observable reality and nomenclatures were constructed from the 18th century, in Latin and in vernacular languages, in order to explore this reality. From primarily being a spreading instrument of ideologies, translation became a tool of knowledge dissemination. In the 17th and 18th centuries, the emergence of literary translation theorists (Pope, Dryden, Nicolas Perrot d'Ablancourt) and the high status of literary and religious translation meant that technical translation was somewhat ignored in spite of the fact that an enormous corpus was being translated. Pharmacy and medicine were the most translated areas, whereas traditional crafts, navigation, and agriculture also were in demand with translators. The internationalization of science in the 19th century meant a growing demand for technical translation. Manuals on technical writing appeared at the beginning of the 20th century (the first one in English is thought to be T. A. Rickard's *A guide to technical writing* published in 1908), although most publications on translation concern literary or religious translations (out of 599 entries in the pre-1950 BITRA catalogue, five are devoted to technical translation) (Aixelá, 2004). Science and technology depend on international communication and although 92% of the world's population live in countries where English is not the native tongue, English, as the lingua franca of science, is dominant in technical texts, although not overwhelmingly so as in fields such as information technology. From the end of the mid–20th century, technical texts in English occupied about half of all technical publications. Even though in particular areas such as chemical literature, more than half of published documents are in languages other than English (Pinchuck, 1977: 16), globally, a majority of publications are driven by the North American market. Statistics published in 2002 by the OCLC (On line Computer Library Center) show that 73% of sites are in English. Scientific and technical Web pages comprise 14.2% of all publicly accessible websites, in second position after sites devoted to information (15.5%).

In spite of the increase of professional documents needing to be translated, the status of technical translators still remains low in comparison to that of their literary peers. Technical and scientific translators, mostly anonymous in the past, are still today largely anonymous, in spite of some visibility in multinational institutions such as UNESCO. In a survey conducted in Germany in 1999, 76% of translators and interpreters were found to work essentially on technical texts, whereas economic texts score 12% and legal documents 6%. Yet, in a country in which many universities are offering courses in technical translation, only 43% of them had chosen to specialize in that area when training (Künzli, 2003: 29). Even though these figures may be different in bilingual or multilingual countries where a full range of documents, in particular institutional texts, need to be translated, they reveal two essential features of technical translation in the world: it represents a huge proportion of the translation market and it is not a glamorous occupation even though technical translators are better paid than their literary counterparts. Throughout the 20th century, training in technical translation tended to be in-service, provided by companies or government departments. Some countries with a strong technical tradition such as Germany have provided training in vocational institutions since the early part of the 20th century, but, in most countries, including America, technical translation courses were not integrated into academic programs until the 1990s. With the growth of translation studies, specialized or technical translation courses, particularly short courses at postgraduate level, are developing exponentially.

Technical Translation: Technical Texts, Style, and Translation Strategies

Text Types, Text Forms, and Terminology

In technical translation, the predominant relationship is not between translator and author, as it is in literary translation, but between the translator and the reader (Bédard, 1986: 178), because the primary aim is to communicate the content of the original message, and not to convey its aesthetic value. A technical translator needs to establish the purpose(s) of the text to be translated and assess the target readership (i.e., level of expertise in the subject matter, scope of the publication, cultural context, register). Technical documents are deemed to be informative, universal, and confined in their subject boundaries, but this is not always the case. Although they consist primarily of informative statements, they may contain expressive elements. Technical brochures for example may be persuasive, although primarily informative, as they attempt to convince an engineer to buy new

machinery for example (Hansen, 1997). This persuasive aspect may be subtly integrated in the document and the translator needs to be aware of the source culture and able to adapt it to the target culture. The field of technology frequently interacts with a range of other fields such as science as well as business, law, and media. Technical documents tend to be devised and written in relation to solidly structured information and are generally contained in established text forms, such as catalogues, reports, articles, instructions, manuals, notices, brochures, and patents. Yet, in spite of this relative textual rigidity, most aspects of technical language are not firmly established. Bédard (1986: 8–21) has shown that not only can the purpose of technical texts be ambivalent, the essence of their language is based on a triple myth: the myth of a well-structured, nonliterary language; the myth of a well-established and exhaustive language; the myth of a language used in a uniform way. The style of technical writing should be clear and concise. It is generally not allusive, but literary language, partiularly through metaphors, be they often coined expressions, is present in technical language. In any case, it cannot be fully structured and established in areas that are in constant evolution, technologically and commercially. In addition, although technical language is prescriptive and defined accurately, it is not uniform, as many lexical items have not been standardized. Synonyms are frequently used simultaneously. One term may be normalized but another with the same meaning, supersedes the official acceptation. Some terms or expressions also can be polysemous, such as 'scale' in English, which has different meanings in different subareas of technology. Terminology is always visible and sometimes frightening at first sight, but it is important to not be too fixated on it and to focus on the message and not on the term or terminological unit out of context. A source language term may not necessarily be rendered with an equivalent target language term. A transposition may be necessary, especially if it is new terminology. If there is ambiguity in the source text, the technical translator's task consists of clarifying the original and ironing out vagueness in meaning. In view of the priority given to the clarity of the target message, translation strategies in technical documents tend to be domesticating rather than foreignizing, to use Venuti's phrase, so as to facilitate transparency. Technical texts aim to be concise and translators often use ellipses (mostly of a part of a term or of a cohesive device) as a strategy to remain brief and accurate. Technical documents are often repetitive, and translators rely increasingly on electronic tools to complete their work. Machine translation systems such as Systran and controlled language devised for specific texts and contexts are used by individuals and a number of organizations with varying degrees of success. The most useful devices are memory tools packages such as Trados or Déjà vu, indispensable for terminology management and extraction.

Youth Language as a Linguistic Phenomenon

Before linguists became interested in them, youth languages were generally consigned to the field of special language research or critique, where they were viewed above, all under the aspect of lexicography. However, under the influence of the so-called pragmatic revolution in communication studies, this focus has widened since the 1980s to embrace a many-faceted interest in the linguistic habits and usages of young people and a methodological pluralism in assembling and classifying empirical data.

Research into this field is currently focused on the following areas: the lexicography of youth languages – the compilation of dictionaries based on the assumption of homogeneous usage; the pragmatics of youth languages – forms of greeting and address, particles, forms of intensification; the ethnography of youth languages – expressive and functional modes of group-specific communication based on concrete examples; oral style analysis – stylistic features and pick-'n'-mix techniques in young people's communication; cultural analysis – functional aspects such as generation-specific delimitation and social identity formation, and sociohistorical aspects of the relation between youth languages and standard languages; and comparative study of youth languages – comparison of code-immanent and code-transcending forms and phenomena.

Far from viewing and classifying youth languages as a homogeneous phenomenon, interdisciplinary research reveals a number of different theoretical approaches.

Theoretical Concepts Applied to Youth Language

Variety

Structurally oriented research generally describes youth languages in the German-speaking area as a variety of German (Standard German). Berruto (1987) saw such varieties as characterized by the cooccurrence of linguistic and extralinguistic features, with situational aspects of language use (social as well as functional) impacting on its concrete forms. Accordingly, how a language is spoken depends on the specific social context in which it is spoken (Berruto, 1987; Neuland, 2003c). Research into French (Scherfer, 2003; Zimmermann, 2003) and to some extent into German youth languages (Heinemann, 1987; Ehmann, 1992; Androutsopoulos, 1998) employs a definition based on the concept of linguistic varieties, defining youth language as a secondary variety – viz.,

Youth Language as a Linguistic Phenomenon

Before linguists became interested in them, youth languages were generally consigned to the field of special language research or critique, where they were viewed above, all under the aspect of lexicography. However, under the influence of the so-called pragmatic revolution in communication studies, this focus has widened since the 1980s to embrace a many-faceted interest in the linguistic habits and usages of young people and a methodological pluralism in assembling and classifying empirical data.

Research into this field is currently focused on the following areas: the lexicography of youth languages – the compilation of dictionaries based on the assumption of homogeneous usage; the pragmatics of youth languages – forms of greeting and address, particles, forms of intensification; the ethnography of youth languages – expressive and functional modes of group-specific communication based on concrete examples; oral style analysis – stylistic features and pick-'n'-mix techniques in young people's communication; cultural analysis – functional aspects such as generation-specific delimitation and social identity formation, and sociohistorical aspects of the relation between youth languages and standard languages; and comparative study of youth languages – comparison of code-immanent and code-transcending forms and phenomena.

Far from viewing and classifying youth languages as a homogeneous phenomenon, interdisciplinary research reveals a number of different theoretical approaches.

Theoretical Concepts Applied to Youth Language

Variety

Structurally oriented research generally describes youth languages in the German-speaking area as a variety of German (Standard German). Berruto (1987) saw such varieties as characterized by the cooccurrence of linguistic and extralinguistic features, with situational aspects of language use (social as well as functional) impacting on its concrete forms. Accordingly, how a language is spoken depends on the specific social context in which it is spoken (Berruto, 1987; Neuland, 2003c). Research into French (Scherfer, 2003; Zimmermann, 2003) and to some extent into German youth languages (Heinemann, 1987; Ehmann, 1992; Androutsopoulos, 1998) employs a definition based on the concept of linguistic varieties, defining youth language as a secondary variety – viz.,

as a secondary system modeled on the primary variety and acquired in the course of secondary socialization (cf. Androutsopoulos, 1998). In contrast to primary varieties, secondary varieties derive from a conscious process of selection and depend on individual factors like lifestyle, interests, and images of the self. Consequently, they differ both in the timing and in the underlying intentionality of their acquisition, and their use is generally restricted to contexts in which, or close to which, they were initially used. As a descriptive parameter, linguistic variety can only grasp some of the relevant features of youth languages: it has difficulties not only with the phenomenon of situational and subcultural variation but also with concepts of communicative process.

Slang

Research in the United Kingdom and North America – and to some extent also in eastern Europe – tends to define youth languages as slang (Eble, 2003; Freimane, 2003), thereby assimilating them again to objects of special language research. This is problematic in its consequences, for it inevitably presents young people as a homogeneous group (cf. Menis, 2003), whereas in reality they and their languages manifest the same sociocultural heterogeneity as the adult world (cf. Henne, 1986).

Oral Style

The sociolinguistic concept of oral style (cf. Dittmar, 1997; Hinnenkamp and Selting, 1989; Kallmeyer, 2000) is also used to describe expressive patterns and structures typical of young people. Neuland's suggestion (1987, 2003c) to apply the concept – developed by Birmingham University's Centre for Contemporary Cultural Studies – of subcultural style as a complex group-specific phenomenon has been taken up on several occasions (Schlobinski *et al.*, 1993; Chovan, 2003), with the emphasis on situationally anchored style in a broadly ethnographic sense (cf. Schlobinski *et al.*, 1993: 40). Style is understood here as a holistic category covering a large number of coexistent and cooccurrent features (cf. Augenstein, 1998; Kallmeyer, 2000), an approach that convincingly reflects the dynamics of young people's communication.

The diversity of youth language is also addressed in the concepts of *bricolage*, reflection, and counterreflection formulated by Clarke (1979) and Neuland (1987). *Bricolage* refers to the pick-'n'-mix technique of young speakers, who select individual elements from the standard speech matrix, decontextualize them and recontextualize them in a youth language framework. While *bricolage* is an important factor in the ongoing regeneration and subcultural differentiation of youth languages, the principles of reflection and counterreflection apply to the sociocultural contexts of youth language, in particular its relations to standard language.

Youth Language and Standard Language

Dynamics of Style Formation and Distribution

The cultural-analytic approach to youth language research enables statements to be made about the influence of youth languages on standard language. With regard to the formation of youth language styles, Neuland (2003c), following Clarke (1979), distinguishes three stages that together form a reflexive loop. 'Style formation' refers to the typical changes – in particular pick 'n' mix – introduced by young people into their language. 'Style distribution' refers to the continuous dilution of these sociostylistic usages, especially by commercialization, and their consequent loss in terms of specific sociocultural connotations. This dilution leads to 'style deletion' as the final phase of the loop. Being a loop, however, the process of style dilution and deletion provokes new style formation and the spiral starts up anew.

Nonstandard Language Formation Tendencies

The constantly changing dynamics of youth language also have a discernible innovatory influence on standard language, especially on its lexis. Random samplings of new or extended entries in standard modern dictionaries (e.g., Duden's *Universalwörterbuch*) indicate a significant growth in the material derived from this sector (Neuland *et al.*, 2003). The ongoing codification of typical youth lexis reveals both expansion and differentiation in the standard vocabulary. In contrast to institutionally instigated change from above, this change from below leads to the development of nonstandard language codes. The process is supported by the idealized social image of youth and the covert prestige accorded to their code as a manifestation of the linguistic substandard (cf. Trudgill, 1972).

Common Features of Youth Languages

Despite the variation and heterogeneity of young people's language, common features can be discerned, including specific features recurring in different languages – e.g., forms of greeting and address, stereotypical phrases and particles, metaphorical and hyperbolical structures, prosodic play (clipping and weakening), neologisms and semantic displacements (cf. Schlobinski and Heins, 1998).

At the morphological level an intensive use of phrasal lexemes and productive word formation patterns is evident, leading – especially via creative affix formation – to the development of word sequences and nests as well as neologisms. As far as lexical development is concerned, this maximizing tendency within youth languages can be observed not only in German (cf. Androutsopoulos, 1998; Bachofer, 2003) but also in British, American, and Australian English (Eble, 2003; Menis, 2003) as well as Latvian (Ernstsone, 2003; Freimane, 2003), Chinese (Zhu, 2003), and Thai (Watananguhn, 2003). The *verlan* used by young French speakers (cf. Gadet, 2003; Hefrich, 2003; Scherfer, 2003) stands out from these in its lexical creativity, with semantic displacement adding new connotations to standard lexemes, as well as neologisms (Zimmermann, 2003).

A further apparently universal feature is borrowing. Here two factors govern selection from the source language(s): linguistic contact and social prestige. German and Latvian youth languages have a predilection for anglicisms, and Saari (2003) demonstrated borrowings from Finnish in the language of young Swedes. German–Turkish code mixing (Keim and Cindark, 2003) and switching (Hinnenkamp, 2003) have been observed in the language of young migrants. In creating their own variants, especially style mixing, young people also exploit the innate multilingualism of standard languages. Dialect usages, for example, have been recorded not only in European (Ehmann, 1992) but also in some Asian youth languages (Zhu, 2003).

Typical syntactic features of young people's language have also been described, but their tendency to parallel the oral vernacular of their respective codes suggests that they are less specific to the group concerned. In this context, German youth languages tend to intensify adjectival phrases, increase the use of qualifying particles, and collapse accusative–nominative use of the indefinite article (Bachofer, 2003). Gadet (2003) observed intransitive usage of transitive verbs as well as a high incidence of unconjugated verb forms in French youth languages.

Written and Spoken Forms of Youth Language

Current research into youth language is increasingly focused on describing written as well as spoken usage. Print media are represented in examinations of fanzines (Androutsopoulos, 1998; Watzlawik, 2000), and increasing Internet use has brought analyses of e-mail, chat room and guest book languages (Androutsopoulos, 2003). A predominantly textual linguistic approach is evident, with contrastive description providing insights into stylistic differences in both written and oral youth subcultures.

In addition to classical lexical features, discourse analysis focuses in this context above all on the conversational strategies used by young people, pinpointing and describing a number of typical communicative techniques with (at times overlapping) genres such as taunting, dissing, and backbiting. These are analyzed functionally with regard to their potential for socialization and identity formation (Androutsopoulos and Georgakopoulou, 2003).

Distinctive Features of Written Youth Language

A characteristic of such texts is the transfer of primarily oral characteristics to the written language. These include the use of expressive idioms, the explicit naming or direct address of interlocutors, and introductory discourse particles. Another popular technique is graphic representation of sound variation by means of vowel or consonant doubling or the use of spoken acronyms, which Androutsopoulos (1998) called 'graphemic marking.' The fictional orality which this induces creates an informal, personal atmosphere between writer and reader. Particularly in informal e-media communication, the tendency towards graphic representation of orality is so pronounced that a strict differentiation of spoken from written linguistic features can no longer be consistently maintained.

Distinctive Features of Oral Youth Language

Analysis of oral peer group usage focuses primarily on typical conversational patterns among young people and their function in processes of socialization and (group) identity formation. The bulk of youth language research in German lies in this field. Thus, Chovan (2003) described how the collective associative speech of young people incorporates positive face work and at the same time creates group identity; Branner (2003) investigated provocative activities such as teasing and taunting in groups of girls; Deppermann and Schmidt (2001a) analyzed dissing as an interactive practice for establishing status relations within male peer groups, and the same writers (2001b), along with Hartung (2001), demonstrated the overall cultural divergence of youth discourse from accepted norms of adult conversation. In communication between young people, universal principles of politeness and thematic focus tend to give way to less rigid norms of interaction – or to disappear temporarily altogether – without this necessarily being taken as a sign of uncooperativeness. Thus, in contrast, to intergenerational discourse, its intragenerational counterpart operates within a sort of free space where the scope and limits of interactive

transgression can be tested and defined without fear of automatic sanction.

Functional Aspects of Youth Language

The socializing function of youth language described above has been further subdivided to meet the requirements of various different theoretical and research emphases. Early work in German concentrated on the linguistic features cultivated by young people to distinguish themselves from the adult generation and their representative prototypes – teachers, officials, and politicians – whose linguistic norms were seen as standing for cultural values that young people often totally rejected. More recent eastern European (Ernstsone, 2003; Freimane, 2003) and Asian (Watananguhn, 2003; Zhu, 2003) studies reveal the same focus. Current western European research highlights the heterogeneity of youth subculture (hip-hop, punk, heavy metal, etc.) and the resulting need for distinctive group markers that provide an inward-looking principle of diversity reflecting the outward-looking one. The argument at this point becomes a matter of the aesthetics of reception, and in this light western European youth languages are frequently seen as indicating not only general boundary-defining strategies but also a wealth of group-specific language games, as well as a tendency to exoticize the trivial (Androutsopoulos, 1998).

Summary

No single perspective can adequately describe youth languages and their functions in all their heterogeneity, for these languages are not only a contemporary but also a historical phenomenon, and their impact on their respective standard languages requires diachronic treatment. Youth languages are not confined to certain linguistic systems; they are an international phenomenon existing in many different languages (Androutsopoulos and Scholz, 1998), and as such they can be analyzed contrastively. Their use is always linked to the intention of the speaker and has distinctive functions, among them the formation of individual and group identities. In this respect they must also be viewed as developmental as well as group phenomena. And in a world where youth culture and subcultures increasingly depend on the media and its commercializing tendencies, youth languages are ultimately also a media phenomenon.

Outlook

Against the background of a globalized world, where the spread of youth languages is supported by the influence of the media, the question arises whether the current heterogeneity of cultural and linguistic phenomena will remain or be supplanted by a growing homogeneity caused, for instance, by preferential borrowing from a single source, such as English, that is commonly endowed by young people with superior prestige. Two features common to all youth languages, however, speak against such an internationalizing tendency: their creativity and their identity (both inward and outward looking). In addition, a glance at the development of youth languages in eastern Europe shows that increasing social liberalization can underpin the development of nationally typical, identity-building linguistic structures among young people. The answer to this question, however, is no clearer than the ongoing development of youth languages themselves, and remains a matter for future interdisciplinary research.

Telephone Talk

T-S Pavlidou, Aristotle University of Thessaloniki, Thessaloniki, Greece

© 2006 Elsevier Ltd. All rights reserved.

During its approximately 130-year lifetime, the telephone has become an indispensable element of everyday life in most parts of the world, connecting people who for social and practical reasons are not in auditory reach. Through this medium a 'distinctive and recognizable genre' (Schegloff, 1993: 4548) of talk-in-interaction has developed, namely telephone conversation. Undoubtedly, it is Conversation Analysis (CA) that is to be credited for having made telephone calls an object worthy of linguistic inquiry (*see* **Conversation Analysis**). Although there had been some interest in telephone conversation before (see Schegloff, 1993, for references), it was through Sacks and the subsequent conversation analytic approach that telephone calls came to feature on the linguistic stage. And yet Sacks' interest in telephone calls was sociologically guided, as indicated in his often-quoted phrase, "We can read the world out of the phone conversation as well as we can read it out of anything else we're doing" (Sacks, 1992, V. 2: 548) (*see* **Sacks, Harvey (1935–1975)**). What, however, made telephone calls more appealing for this ethnomethodologically grounded type of sociological investigation than other sources of naturally recorded data was that telephone calls stood up to a number of fundamental (theoretical and methodological) imperatives of CA; most notably, telephone data, through their constitutive lack of visual information for the participants involved, allowed the possibility of *-emic* analyses of the interaction, i.e., the analyst had at his/her disposal the same kind and amount of information that was available to the participants themselves in the interaction. Coupled with additional features, some shared by other types of naturally data recordings (e.g., that they can be subjected to scrutiny as often and by as many analysts as one wishes), others being incidental to the specific sociohistorical setting of that research (e.g., that certain U.S. institutions, such as emergency centers, independently made recordings of incoming calls), telephone talk came to play a pivotal role in the conversational analytic approach.

In a series of very influential papers (e.g., Schegloff, 1968, 1986, Schegloff and Sacks, 1973), powerful analyses were provided and the sequential organization of talk in the opening and closing sections of telephone calls was meticulously established. Openings, it was propounded, comprise four core sequences: (a) summons-answer: the telephone rings and the person called picks up the phone and responds to the calling signal, initiating a working channel of communication and displaying availability; (b) identification/recognition: the identities of caller and answerer are ensured through self-identification or other recognition; (c) exchange of greetings; and (d) exchange of tokens of phatic communion (how-are-yous and responses). Closings, on the other hand, were shown to consist of two core sequences: (a) offering to close (preclosing) and accepting to do so; and (b) exchange of farewells, provided that the preclosing is positioned at "the analyzable end of a topic" (Schegloff and Sacks, 1973: 305). As has been variously stressed, 'canonicity' in this framework does not imply that all calls (not even most calls) unfold in the prototypical way. But variation on the basic format was handled primarily as a means toward unraveling the sequential organization of telephone conversation, either by demonstrably showing it to be a result of structural requirements or by helping in modifying hypotheses about the underlying patterns. When the CA studies on telephone calls got gradually to be known (outside the United States or the CA community), however, variation was also approached from a different angle: to what extent are the CA findings independent of the fact that the data, i.e., American English telephone talk, come from a particular culture only?

In the first two decades after Schegloff's seminal work on openings in the late 1960s, research on telephone calls outside (as well as within) the CA paradigm was not in abundance, and the sporadic studies challenging the CA findings on openings were flawed at least in that they did not rely on recorded telephone calls. By the beginning of the 1990s at the latest, however, the topic of variation was explicitly taken up by a CA proponent, Robert Hopper, most prominently in a book devoted to telephone conversation and focusing, in particular, on openings: "A culture's telephone customs display tiny oft-repeated imprints of community ethos. Ask any traveler, immigrant, or ethnographer about telephone conversations in countries outside the USA. You will hear about differences" (Hopper, 1992: 85). Apart from the late Hopper and his associates, an increasing number of researchers, using recorded data, have been reporting differences, along with similarities, in telephone calls around the world (for references, see Luke and Pavlidou, 2002a). The lion's share of this research deals with openings, whereas to date only a small number of studies on closings is available. One of the reasons for this division of labor is

presumably the complexity of closings, which have to take into account all the preceding talk in the phone call and at the same time face the risk of being redefined as yet another stretch of conversation before ultimately ending the call.

In research on telephone calls in languages other than English, a topic that has inevitably attracted attention has been the language specific options and the way that these are exploited in the accomplishment of the phone call. For example, Park (2002), in her study of Japanese and Korean openings, has demonstrated that the contrastive connectives *kedo* (Japanese) and *nuntey* (Korean), when used in self-identifications, signal that the reason for calling is of immediate concern and give the call a business-like tone. In addition to the language specific means, the particular forms in which the core sequences are realized in different linguistic communities have been explored. Houtkoop-Steenstra (1991), for example, has shown that in Dutch openings the answer to the summons is accomplished through self-identification by name, instead of using something similar to *hello*; moreover, it has been suggested that self-identification is the preferred mode in the Netherlands over other-recognition in the United States – a preference also encountered in other Northern European countries as contrasted to, e.g., Greece. A further issue concerns the relative prominence of the individual components of the canonical opening: although the summons–answer sequence is, by its nature, an obligatory constituent of openings, the greetings or how-are-you sequences seem to get varying relevance across cultures, effecting, among other things, reductions or extensions of the opening. Greetings, for example, have been found to be an integral component of Swedish openings (Lindström, 1994) but dispensable in Greek ones (Sifianou, 2002); phatic utterances of the how-are-you type, by contrast, were shown to be prominent in Greek openings (a point also stressed for Chinese openings [Sun, 2004]), but much less so in German ones (Pavlidou, 1994). This foregrounding of the interactional aspects of communication has been multifariously highlighted, e.g., in terms of the recipients' social status as in *taarof* (ritual politeness) in Persian openings (Taleghani-Nikazm, 2002) or in terms of playfulness and humor (see, e.g., Antonopoulou and Sifianou, 2003, for Greek openings); it also has been shown to affect the organization of closings (for Ecuadorian Spanish, see Placencia, 1997; for Greek, see, e.g., Pavlidou, 1997, 2002).

In contrast to Hopper, who – retaining an intrinsic-to-message view of variation (1992: 72) – claimed that despite divergencies the canonical opening still holds across cultures, other researchers challenge such a "universalist" position. This tension may be resolved if, following ten Have's (2002) proposal, emphasis is given to a functional rather than the structural perspective, which has been more prominent in CA. Of greater consequence, however, seems to be the fact that research on telephone talk has not always been guided by the same motivations and aims as CA, some of it having been called "contrastive cultural analysis"; according to Schegloff (2002), the latter presupposes a within-culture analysis that is grounded in the details of the data and establishes its convergence with the participants' understandings. What is at stake, then, is the transfer of analytical tools developed within one paradigm to a different one without warranting the epistemological prerequisites that necessitated these tools in the first place. Even so, research on telephone talk has occasioned a growing body of naturally recorded data from different linguistic communities and spawned a number of analyses that have proven to be pertinent for areas such as, e.g., foreign language teaching, inasmuch as telephone talk appears to be a sensitive area in intercultural encounters.

Although certain fundamental features of the phone call have basically remained the same (dyadic nature, lack of visual information), the technical apparatus involved has undergone considerable changes over the years (cordless phones, answering machines, automatic number identification, caller's categorization/identification through ringing melodies, etc.), some of which, like caller identification, have direct effects on the structure of the call. Undoubtedly, the most dramatic innovation, encompassing a number of the features just mentioned, has been mobile telephony. Whereas systematic work on the impact of this technology on society is already available, research on the structure of mobile talk based on recorded data is only beginning, so that claims about changes in the organization of conversation (not to mention variations on expectedly different canonical patterns) effected through the transformation of the medium cannot yet be substantiated. Mobile telephony has contested, at least quantitatively, the traditional mode of calling: reports on the spread of mobiles indicate a 'penetration' [*sic*] of over 80% for local markets as different as Hong Kong (cf. Bodomo, 2002) and most West European countries (The Netsize Guide, 2004). By contrast, telephony as a whole seems to have gained impetus and consolidated its place among communication technologies, a place that would otherwise have been most seriously threatened by, e.g., e-mailing.

The broadcasting of televisual signals to the general public began in the United Kingdom in 1936 but only to a very small number of people within a limited range of London. It was discontinued once the Second World War began. It is therefore probably right to think of television broadcasting as a phenomenon of the postwar period, spreading widely across the world during the 1940s and 1950s. By the 1950s it was firmly established as the dominant mass medium in most developed countries, a position it continues to cling to despite a serious challenge from the Internet.

The development of television both in terms of its organization and of its content initially followed that of the domestic medium it displaced, radio. Like radio, the initial system was a commercial one in the United States and a publicly funded one in the UK and most of continental Europe. Australia, typically, adopted a hybrid of the two, but then did not begin until 1956, three years after commercial television had commenced in the UK. The U.S. Public Broadcasting System, which has operated since 1967, does not have the same funding support or relationship with governments typical of public broadcasting in other countries. It is now most common for television systems to operate a combination of commercial and public broadcasting – the public broadcasting monopolies that operated in many northern and eastern European countries long after advertising became commonplace on British television, disappeared following the arrival of satellite broadcasting, which observed no national boundaries.

The content of early television followed radio in being heavily talk based, not only because this was

The broadcasting of televisual signals to the general public began in the United Kingdom in 1936 but only to a very small number of people within a limited range of London. It was discontinued once the Second World War began. It is therefore probably right to think of television broadcasting as a phenomenon of the postwar period, spreading widely across the world during the 1940s and 1950s. By the 1950s it was firmly established as the dominant mass medium in most developed countries, a position it continues to cling to despite a serious challenge from the Internet.

The development of television both in terms of its organization and of its content initially followed that of the domestic medium it displaced, radio. Like radio, the initial system was a commercial one in the United States and a publicly funded one in the UK and most of continental Europe. Australia, typically, adopted a hybrid of the two, but then did not begin until 1956, three years after commercial television had commenced in the UK. The U.S. Public Broadcasting System, which has operated since 1967, does not have the same funding support or relationship with governments typical of public broadcasting in other countries. It is now most common for television systems to operate a combination of commercial and public broadcasting – the public broadcasting monopolies that operated in many northern and eastern European countries long after advertising became commonplace on British television, disappeared following the arrival of satellite broadcasting, which observed no national boundaries.

The content of early television followed radio in being heavily talk based, not only because this was

how a medium targeted at the home was seen to operate and what those performing on it were experienced at, but also because the small screens and the low resolution (especially in the United States) did not encourage lavish spectaculars or material heavily dependent on visuals. Even today, with more countries providing high-definition television and screen size growing substantially, it is still a well-supported cliché of media studies that while film is primarily a visual medium, television is an aural one.

John Ellis (2000) has talked of the three ages of television: scarcity, availability, and plenty. In the early stage, which lasted until the late 1970s and in places into the 1980s, public broadcasting was able to flourish in most countries because the electromagnetic spectrum was regarded as a limited resource, the allocation of which needed to be monitored by government agencies and thus the operation of television needed to be conducted in the public interest. Even when the combination of commercial and populist forces introduced services which saw entertainment as their prime motive, regulation constrained them to provide some serious nonfiction content. This was also a period of televisual scarcity in other ways, including the number of competing channels and the hours broadcast each day.

Ellis's televisual age of availability is what most viewers continue to experience. It developed during the 1980s in parallel with other sociopolitical and economic changes emphasizing the centrality of consumer choice. The number of channels proliferated and the previously dominant (in the United States, the big networks; in Europe, public broadcasters) felt much less secure in their role and position. A much greater choice of channels and programs was available through cable and satellite delivery and no longer were single programs likely to be watched by large proportions of the nation. Fragmentation had arrived. The distinction between this age and that of plenty is far from strict. Significant proportions of the European and American population exist in the third age now, thanks to the extra services available through digital delivery and personal digital recorders. Ellis argues that branding has become the way in which plenty is managed, both by identifying particular television services (Discovery, the History Channel) and by extending the reach of individual programs, not only through related spinoff programs, but in the case of the currently popular cooking programs, for instance, through spinoff merchandise (Ellis, 2000: 165–169).

Technological developments are important to this outline, but other devices, most especially the remote control and the VCR, were at least as significant in changing the way in which people watched television. Both remotes and VCRs (now being replaced by DVD recorders) enabled more television to be watched (or surfed) and, where commercial services were concerned, more commercials to be omitted. Since free-to-air commercial television is funded by advertising, this required compensatory actions, of which placements have been the most pervasive. The VCR and the DVD are perhaps more significant for the relationship of television and language because either through off-air recording or sell-through video or DVD, favored broadcast programs can be watched and rewatched and their minutiae savored.

From the beginning, television, like radio, broadcast both fictional and nonfictional programming. Many of the genres of radio transferred: nonfictional programs such as news, current affairs, documentaries, advice programs, and quiz shows; fictional ones such as plays, serials, and comedies; and programs such as variety shows and concerts for which the fiction/nonfiction distinction is not really relevant. The closeness to radio rather than to film acted in conjunction with the quality of the image received and the distracted character of the attention given by viewers to prioritize speech, both the direct-to-camera speech which dominated the nonfiction programming and the indirect which characterized the fictional. For public broadcasting, the important programs initially were the nonfictional ones, with news, current affairs, and documentaries important both for nation building and producing an educated informed electorate. Fictional programs provided entertainment to attract viewers to the channel or, in the case of televised versions of great works of literature, formed part of the 'civilizing mission' of public broadcasters such as the BBC. For commercial programmers the more serious nonfictional programs were required to maintain the licenses necessary to operate, but the fictional shows drew more viewers to be sold to advertisers.

Television news services do attract viewers in large numbers, though; the main bulletins on the more popular free-to-air services are high rating and it is television that most people cite as their principal means for being informed about public affairs; cable news networks survive and thrive during times of crisis. Documentaries are also a popular nonfiction genre with dedicated pay television services, but it is popular history and above all nature documentaries that dominate the grouping. The lighter types of nonfiction programming – quizzes and advice shows – have been the ones which have proliferated and, especially in the age of availability, come to dominate nonfiction programming. Quizzes and game shows, the latter able to take advantage of television's visual capability to test physical as well as intellectual

dexterity, provide valuable occasions to incorporate ordinary people into programming and increase the air of sociability so valuable to a mass medium, as Paddy Scannell (1996) has pointed out for both radio and television. He claims sociability, exemplified in conversation, to be broadcasting's most fundamental communicative ethos (Scannell, 1996: 23), which will be explored further below.

The same incorporation has become the case for advice programs, though this took much longer to occur. It was well into the age of availability when the combined pressures of consumerism and audience inattention to commercial breaks lead to a reconfiguration of advice programs into lifestyle shows. As I discuss elsewhere, lifestyle programs have incorporated house and garden, cooking, holiday, and health programs to guide choices between available products and encourage the maintenance of a continually modulating self defined in large part by these very acts of consumption. Most commonly, such guidance is performed around the bodies of ordinary people who, for example, have their houses or their bodies made over in the course of a program (Bonner, 2003).

Some writers, in particular John Corner, extend the field of documentary to include the newest type of nonfiction television programming, so-called reality television. His argument that the functions of documentary should be extended to include 'diversion' is a convincing one and allows such programs as *Big Brother*, valuing sociability and depending on the willingness of ordinary people to perform 'ordinariness' to camera in the hope of being transformed into celebrities, to be included as part of a continuum of 'documentariness' within nonfiction television (Corner, 2002).

When talking of fictional genres, it is particularly necessary to acknowledge the complexity of the term 'genre.' For television, it is used to refer both to primarily structural and to primarily narrative components. On the one hand, it talks of the form of programs – whether they are continuing serials or more episodic series, or whether if comedies they are sitcoms or sketch shows – and on the other it may refer to the content, either through setting (hospital dramas, westerns), events (law and order shows) or premise (science fiction programs). Steve Neale has argued for considering television programs as engaging in 'multiple generic participation'; thus the British program *Casualty* is both a television series and a hospital drama (Neale, 2001: 4). While certain fictional genres, like spy or western series, go in and out of fashion, others, especially law and order series, hospital dramas, and family sitcoms, remain televisual staples.

Before considering specific ways in which language and television interact, it is necessary to consider two other determinants of televisual programming – scheduling and source of show. Scheduling is a very different affair for the free-to-air channels, which screen a great range of genres, as opposed to pay channels, which may be dedicated to a particular genre. The art of scheduling is to match programs with the most appropriate audiences in terms of maximizing ratings and minimizing costs. For free-to-air the fiction is maintained that television is watched by members of conventional nuclear families – thus, the morning and early afternoon is designed for housewives, late afternoon for children, followed by early evening family viewing, which begins prime time, and then adult viewing as children are put to bed. The address and the language used thus modulate across the course of the day, as does the amount of sex and violence allowed.

Programs are sourced in three main ways: they may be locally made either by the channel or network itself, as is usually the case for news for instance, or by independent companies commissioned by the networks; they may be imported from other nations; or they may be made to a purchased format. The term 'format' can be used simply to refer to what I have previously considered a conception of genre – a magazine show or a sitcom. Here, however, I am using it to refer to a tradable outline of a program which enables, for example, at present more than 100 countries to have viewed *Who Wants to be a Millionaire?*, most of them in local editions. Formats may be used for both fictional and nonfictional programs and while the international trade in complete programs is dominated by the United States (which imports less than any other country), the trade in formats is much less unilateral (see Moran, 1998). Importing the format alone allows a proven success to be adapted to local conditions, not only increasing local employment, but also avoiding the necessity of choosing between subtitling or dubbing foreign languages or having nonlocal versions of, say, Spanish or English dominating the airwaves.

Language Used on Television

The range of language used on television is only a fraction of the range of language used in the societies in which it operates and some of it is specific to the site, but the range has increased over the time that television has existed as a mass medium. Initially, television programs, especially the nonfictional ones, adopted comparatively formal speech and modes of address. The BBC for instance used the dominant educated Received Pronunciation across news,

current affairs, documentaries, and advice programs, even for sporting commentary. Local dialects were permissible for comedy and for fictional programming with claims to social realism, as was the case for early soap operas such as *Coronation Street*. Australian programming both on public and commercial channels preferred voices closer to (RP) British inflections. U.S. networks too called on a limited range of dialects, preferring those dominant among the middle classes in the major production centers of New York and California. The social shifts of the 1960s encouraged a greater range of sounds to be seen as socially acceptable and regional dialects began to be heard even nationally on British television, with similar moves to variation elsewhere. The same forces also encouraged a more casual delivery. Because television, again like radio, is continuously broadcast and primarily received either individually or by small, mainly domestically situated groups, it needs to have ways of attracting attention and managing the intimacy of the ostensible interaction. Of course, it is not an intimate occasion. A person sits in a studio speaking to camera surrounded by a substantial group of unseen other people and addresses an audience which may be numbered in the millions. Or a group of actors perform a script in studios and on location to be compiled into a soap opera episode again received by a vast audience, but this time dispersed across the globe and over a considerable period of time. One of the ways of dealing with this, which applies to the first situation, is to use direct address, talking to the viewer as if they were present face to face for a two-way communication, employing a range of devices including commands that may acknowledge their location ("don't try this at home"), assumptions about shared understandings ("you may have thought you already knew everything about growing begonias, but . . .") and personal salutations ("goodnight from me"). Here the television presenter makes assumptions about viewers from which to construct a monologue that sounds as if it may be dialogic. Again the interaction assumes a sociable role.

Robert Stam has discussed what he calls the 'phantasmatic' relationship between viewer and television presenter, examining especially the "fictive we" (Stam, 1983: 38–39). This refers to a shifting collective named by the television presenter who may appear to speak for the program ("we'll be back after this break"), the nation ("we Americans like to think of ourselves . . ."), or a grouping that includes both television professionals and viewers ("we've all had that experience of . . ."). Despite the fact that those included vary so much, the actual referents remain clear despite their fundamental fictionality.

The peculiarity of the simulated relationship between presenter and television viewer was examined very soon after it became standardized. Donald Horton and R. Richard Wohl coined the term 'parasocial interaction' to describe it in 1956. As they note, "the interaction, characteristically is one-sided, nondialectical, controlled by the performer and not susceptible of mutual development" (Horton and Wohl, 1956: 215) yet it produces an illusion of intimacy. They concentrate on the way presenters of nonfiction programs interact with studio audiences, but acknowledge its applicability for more distant 'lonely viewers' of fictional programs. The term has been taken up to explain the overinvestment of some audience members in the lives of soap opera characters, but is most found in analyses of viewer relations with newsreaders. The common practice of viewers responding aloud to the greetings and farewells of their regular newsreader as if there were indeed an actual relationship between them is seen as indicative.

The various ways in which the simulated copresence of television performer and viewer is referenced is aided significantly by the centrality of 'liveness' to the televisual medium. Whether or not a program is actually broadcast simultaneously with its production, elements of liveness may be claimed by such rubrics as 'recorded live in front of a studio audience.' Elements of liveness, often just linking commentary between prerecorded segments as is the case for news bulletins, are industrially regarded as adding value to a broadcast. The presenter or commentator experiences the events being broadcast at the same moment as the viewer and may share similar emotions – of excitement at a sporting performance or horror at a disaster such as September 11.

The problems of address are not so evident in the many television programs that rely on various forms of interviewing. Most nonfiction programs include interviews as one of the ways in which information is gathered and disseminated. These may be very brief exchanges, as found in the news, where interviews have largely been replaced by sound bites for the more important stories, or the entire content of programs such as celebrity chat shows. The interviewer usually stands as an intermediary between the viewer and the person being interviewed, at times posing questions directly as on the viewers' behalf. Paddy Scannell's (1991: 1) suggestion of the 'double articulation' of broadcasting addressed to those actually present but with the intention of being heard by those attending distantly applies to this as to most television other than the sole presenter speaking to camera discussed above.

Philip Bell and Theo van Leeuwen have categorized media interviews as revelatory, adversarial, or

conversational. They emphasize that these distinctions arise from the relationship between the media institutions and viewers. Adversarial interviewers ask questions of politicians, for example to test their honesty on behalf of the audience constituted as citizens, while conversational interviewers on chat shows test out the foundations of celebrity for the viewers, invoking their concerns if challenged by interviewees (Bell and van Leeuwen, 1994: 222–224). Revelatory interviews are often structured with confession following an introduction to be followed in turn by reflection and testimony (Bell and van Leeuwen, 1994: 93). They are the least common but while Bell and van Leeuwen use a religious radio instance, they can be seen to be the key form for talk shows such as *Oprah*.

Not only is spoken language particularly important for the medium of television generally, but some programs prioritize it even further. Laura Stempel Mumford (1995: 43) has observed of soap opera, "I see the primacy of talk, the telling and retelling of stories, as a function of the programs' concentration on personal relationships and the continual efforts to construct a particular kind of community". Drama series, especially crime ones, are able to include significant action sequences, which reduce the extent to which talk is central, while music programs and sports broadcasts have their key concerns elsewhere, but dramas of relationships, not just soaps but usually also sitcoms, and the majority of other comedy shows rely on what is seen more frequently as the bane of nonfiction programming, the 'talking head.' It is clear that it is those fictional programs which most reflect the domesticity of the site of reception that are dominated by talk.

To say that talk is unimportant for sports programs is only a comparative claim. Although it would be possible for matches and other contests to be screened without commentary, this does not occur and the character of sports commentary is much investigated. Judy Delin (2000) examined the distinctive intonation, used to create excitement, and the consequences of the imbalance of power between commentator and expert, noting how turn taking based on the latter can be overridden by the importance of the description of action.

The talk show built around the intimate problems of selected viewers is a distinctive televisual genre. Much critical reception sees them as providing an embodiment of the feminist slogan 'the personal is the political' through opportunities for ordinary people, especially women, to represent their own problems, though there are concerns about the class relations exhibited when the ordinary people are so regularly working class while the presenters and advisers are middle class. The shows are regarded as one of the key sites for the spread of therapeutic discourse across television. For most of the programs, the double articulation involved assumes that the confession of the problems and the solutions suggested by the experts provide a "talking cure" (Shattuc, 1997) for those present as well as those viewing, though this may not apply to the more confrontational examples, such as *The Jerry Springer Show*. A good representation of the wealth of international critical writing on the field is provided by Tolson (2001).

Confession is a common mode for television not only in the interview context or the talk show. A key feature of reality game shows such as *Big Brother* is the provision of a confession closet where individuals escape from the situation manufactured by the producers to speak directly to the viewers about matters they would rather not be overhead discussing by their fellow participants. While in *Big Brother* the confession is made to the titular figure (and may even involve an interrogation of the confessor), the addressee of the confession in other programs constitutes viewers as privileged if unseen recipients of private information are made public. These are particularly telling instances of the blurring of the public and the private that contemporary television so insistently performs. Although there is no technical requirement for it, the visual resolution of material is often degraded compared to the rest of the program, as if to index its 'secret' dimension.

The development of a new range of programs in the age of plenty with the proliferation of channels all requiring content has led to a need for new names for the genres. Some terms are hybrids of previously separate categories, as is the case with 'infotainment,' while others, such as 'talk shows' and 'reality television,' take one aspect of the new genre and use it for the title. All three of these instances have significant potential for confusion. 'Infotainment' names house and garden or lifestyle programming in the UK and Australia but lighter, more entertaining, current affairs in the United States and continental Europe. 'Talk' is often used to name both social problem and celebrity interview programs. The greatest range is that covered by 'reality TV.' Initially used in the United States to name cheap fly-on-the-wall programs made while riding along with emergency services, it was a little later also applied to game shows which sent ordinary people in as contestants to created situations requiring them to survive physical threats (*Survivor*) or extreme boredom (*Big Brother*) while hoping to outwit their fellows to win fame and fortune. In the United States 'reality television' is now used to name virtually all nonfiction programming other than news, while elsewhere it is restricted to

docusoaps and reality game shows – the term now most common to describe *Big Brother* and its ilk. There has been no need for new names for fictional programs since generic variation here has all been within the existing range.

Language Taken from Television

One of the problems facing the study of television is the difficulty of proving that television influences the behavior of viewers. Even in the heavily researched area of television and violence, the evidence is contradictory. When it comes to the matter of demonstrating that television influences the language of viewers, much of the research works from observation and anecdote or develops from media panics (usually) about the decline in standards or the adoption of foreign locutions. The area is less contentious than the television violence debate or the extent to which televisual junk food advertising encourages childhood obesity, so there are few studies arguing against a televisual component to changing language use.

The most characteristic type of media panic about television's influence on everyday language is nationally inflected and involves perceived threats to traditional speech practices by the adoption, usually by the young, of foreign locutions and slang. The French distaste for the incorporation of English terms and phrases, some of which have a televisual origin, is a variant of this, but because imported television programs are subtitled or dubbed, television is not often singled out for particular attention. In countries that share English with the dominant exporter of television programs, the United States, concern about the spread of 'Americanisms' and the dilution of British or Australian forms of English is more often blamed on television.

Though the percentage of imported American entertainment product is greater for film, the far greater amount of television watched (including films screened on television) leads to television being seen as the principal threat. This is compounded by the television set being the device on which videos and DVDs of imported American entertainment, now including large quantities of 'sell-through' television programming, are watched, often again and again. Unlike film, where series are comparatively rare and appear only after considerable time has elapsed, television characteristically screens programs as series or serials which appear weekly, or even more frequently. This also provides repeated exposure to favored programs and characters, the clothing or speech patterns of which may be emulated and spread throughout particular age-groups and beyond.

One of the few thoroughgoing studies to investigate some of these assertions is Michael Adams's work on *Buffy the Vampire Slayer*. Adams has both analyzed the role of language on and off the program and provided a lexicon of 'slayer slang,' although he is not concerned with the spread of the slang beyond the United States. He claims that "because *Buffy* is so linguistically potent, its cultural influence amounts, in part, to influence on American speech" (Adans, 2003: 11). Much of his argument concerns the way slayer slang spreads rather than starts slang usage, identifying many instances where expressions regarded as quintessentially coming from the 'Buffyverse' have previous more limited appearances; for example, "without denying its rising popularity in general American slang, 'über-' is undeniably a slayer slang prefix" (Adams, 2003: 52). He claims consequences beyond the linguistic in saying that "the show's continual use of slang, not to mention its running commentary on the English language, successfully dignifies teen language and the range of teen experience for which it speaks" (Adams, 2003: 28). 'Bail,' meaning to leave or quit, is an example of one of many slang terms adopted from *Buffy* by young Australians; Adams discusses it as being first used in the *Buffy* film in 1992 and being representative of a common practice of clipping phrases (in this case 'bail out') inherited from the 1960s (Adams, 2003: 39).

Both fictional and nonfictional shows can operate in this way. Jamie Oliver's cooking programs provided a vector for the dissemination of 'mockney' usages, such as 'dodgy' or 'pukka' or the clipped comparative 'easy as,' across Australia not long after his first show aired. Advertising slogans also can be observed transferring readily from television commercials (among other sites) into everyday speech, often passing through comedy sketch shows on the way.

Not producing any level of panic is the similar practice of adopting catchphrases from popular television programs. Most commonly these relate to a particular program, or even a particular character, and can be used to demonstrate allegiances, as would be the case with someone calling on *Star Trek: The Next Generation*'s Jean-Luc Picard's phrase 'make it so.' Occasionally, they can be more thoroughgoing in their televisuality. Perhaps the strongest of these is 'here's one I made earlier,' evident in almost all instructional television programs though most present in cooking shows. It provides testimony to the valuation of liveness and the illusion of instruction happening in real time, since viewers are fully conversant with editing to cover time lapses in other genres. It has now become such a cliché that it is no longer possible for television presenters to use it unironically. Cult programs, such as *Monty Python's Flying Circus*

or *Fawlty Towers*, may provide both long phrases and short references to sketches – 'dead parrot' from the former and 'don't mention the war' from the latter – which are comprehended far beyond the actual audiences for any of the originating shows. The latter phrase in particular is a great favorite with newspaper subeditors.

The importance of talk in soap operas, mentioned above, follows through to a recognized feature of everyday language, the use of television program content to facilitate discussion about other matters. Chris Barker (1999) has explored the way British Asian girls draw on soap opera plots and characters to help manage the ethical and moral dilemmas they face. This follows earlier work on the way people talk about soap opera and use the programs to talk about issues of importance to them (e.g., Hobson, 1989).

The popular adoption of words and phrases from television is now much aided by associated websites. Adams (2003: 6). noted the importance of the various *Buffy* fan-sites not just for disseminating slayer slang but also for developing it and, given the program's writers' attention to such sites, feeding back in to the program Official websites and spinoff merchandise are also involved. The Australian cult sitcom *Kath and Kim* not only coined terms such as 'hornbag' which appeared on aprons and T-shirts and moved into popular usage with aficionados, but also provided a pronunciation section on its website to ensure that viewers could practice the precise intonations of ordinary words like 'issues' as spoken by Kath or Kim ('iss-ewes') or other characters on the program.

It seems likely that more countries will move into the televisual age of plenty, but because most of this plenty is associated with subscription rather than free-to-air television, the greater number and range of programs will not be available to all. Television has been a site for unifying national rituals; in an age of scarcity highly popular programs could be viewed simultaneously by a large cross-section of the population and information and catchphrases from them moved rapidly through societies. Now it takes huge public disasters such as 9/11 or sporting events such as the Olympics to draw these kinds of audience; programs are more commonly seen by small fragments of the population and the linguistic consequences are more limited. Even so and despite the competition from other media for people's attention, television continues to simulate copresence, talking away to us in our domestic spaces about domestic issues, about politics, about our fantasies and our passions and for the most part doing so in a highly sociable manner.

Introduction

Telugu is one of the four literary languages of the Dravidian family. It is mainly spoken in the state of Andhra Pradesh in India. According to the official Census of India (1991 report) there were 66 million speakers of Telugu in the country. The state of Andhra Pradesh could be demarcated into four major dialectal regions (North, South, East, and Central). Varieties of Telugu spoken outside this state differ to a good extent from these main dialects. Like many other languages in India, in addition to regional variants, Telugu possesses a good number of social variants too. Both these variations—regional as well as social—are reflected in most of the components of the language viz., lexical, phonological, morphophonemic and grammatical. Telugu script is a derivative of the Southern Brahmi script. Though Telugu words are found in inscriptions dating back to 200 BC, we get the first inscription written entirely in Telugu sentences in 575 AD. The major literary works in Telugu start from the eleventh century BC.

Sounds

Its phonemic system contains native as well as borrowed sounds (from Sanskrit, Perso–Arabic and English sources). All nasals, trills, approximants, and laterals are voiced; all fricatives are voiceless; stops are differentiated both for voicing and aspiration (Table 1). Aspirated stops are found only in educated and Sanskritized speech – even in that, /th/ is rarely found and the /th/ sound in the Sanskrit original is mostly replaced by /dh/ except after /s/. /f/ is found in words borrowed from Perso–Arabic and English sources. /ph/, which is available only in words borrowed by Sanskrit, is generally pronounced as /f/ in non-Sanskritic but educated speech. /s/ and /š/ are mostly merged into /s/ in non-Sanskritized speech. /w/ phonetically varies between [w] and voiced labio dental approximant [ʋ].

Vowel harmony plays an important role in its phonology (Table 2). At allophonic level, the height of a vowel controls the height of the vowel that precedes it (in the preceding syllable), for example, 'cat' */pilli/* > [*pilli*]; 'girl' */pilla/* > [*pIlla*]. Sandhi changes are also very complex in the language. These include short-vowel deletion, assimilation of consonants for place, manner, phonation type, and so on. Application of these extensive Sandhi changes sometimes results in telescoping of several words into long strings. For instance, when some of the Sandhi rules are applied on the underlying form of the sentence: *wēḍi-nīḷ ḷu-lēwu-aṇṭāwu-ā* 'Do you say that there is no hot water?' we get the output as: *wēṇṇīḷḷēwaṇṭāwā*.

Pronouns and Pronominal Categories

Pronouns are differentiated for the features of person, number, human-maleness, and humanness. The pronouns are *nēnu* (1s), *mēmu* (1e-pl), *manamu* (1i-pl), *nīvu/nuvvu* (2s), *mīru* (2pl), *wāḍu* (3s-mh), *adi* (3s-nmh), *wāru/wāḷḷu* (3pl-h), *awi* (3pl-nh) (1 = 1st person, 2 = 2nd person, 3 = 3rd person; s = singular, p = plural; e = exclusive [excludes the addressee], i = inclusive [includes the addressee]; mh = human male, nmh = other than human male; h = human, nh = non-human). This classification of pronouns is fundamental, as it is reflected in the pronominal suffixes that are suffixed to the finite verb stems in forming full verbs (a process also known as 'verbal concord or agreement'). The major allomorphs of the pronominal suffixes are 1s: *-nu*, 1e-pl/1-pl: *-mu*,

Table 1 Consonants

	Labial		*Labio dental*	*Denti-Alveolar*		*Alveolar*	*Retroflex*		*Palatal*		*Velar*	
Stops												
Unaspirated	p	b		t	d		ṭ	ḍ	č	j	k	g
Aspirated	ph	bh		(th)	dh		ṭh	ḍh	čh	jh	kh	gh
Nasals		m				n		ṇ				
Fricatives			f			s	ṣ		š		h	
Trills						r						
Approximants										y		w
Laterals						l		ḷ				

2s: *-wu*, 2pl: *-ru*, 3s-mh: *-du*, 3s-nmh: *-di*, 3pl-h: *-ru*, 3pl-nh: *-yi*. In the category of third-person pronouns, in addition to the remote pronouns given above, we also get proximate and interrogative pronouns. All the third-person pronouns are listed below, along with their oblique forms (that are explained later).

The 2pl and 3pl-nh pronouns are also used as honorific ('respect') pronouns. When honorificness is taken into account, in third person we get extra sets of pronouns that denote different degrees of 'respect.' The sets of pronouns with increasing degree of honorificness are 3s-mh REMOTE *wāḍu atanu/āyana, wāru*; PROXIMATE *wīḍu, itanu/īyana, wīru*; INTERROGATIVE: *ewaḍu, ewaru*; Third-person singular human feminine (as nonhumans are not differentiated for honorificness): REMOTE *adi, āme/āwiḍa, wāru*; PROXIMATE *idi, īme/īwiḍa, wīru*; INTERROGATIVE *ēdi, ewarte, ewaru*. Note that the pronouns with highest degree of honorificness (*wāru, wīru, ewaru*) are originally one of the alternants of the Plural human forms (but the other alternants viz., *wāḷlu, wīḷlu, ewaḷu* are not used as third-person honorific singular forms).

Oblique Forms

Nouns (simple, derived as well as plural forms) and pronouns have both direct and oblique stems. The direct stems are the nominative forms (direct stems of singular nouns and ever-plurals (e.g., *pālu* 'milk') are listed in the lexicon), whereas the oblique stems are used in several of the case inflections. In the case of some nouns, both of these stems are same in form (e.g., *kukka* 'dog': *kukka-ki* 'to a dog'). In the case of all pronouns and some nouns, the oblique stems differ in shape (e.g., *rāyi* 'stone': *rāti-tō* 'with a stone'; *kukka-lu* 'dogs': *kukka-la-ki* 'to the dogs'). The oblique stems of third-person pronouns are given in Table 3. The oblique stems of the personal pronouns are *nā* (1s), *mā-* (1e-pl), *mana-* (1i-pl), nī- (2s), *mī-* (2pl).

Noun

A noun is simple (monomorphemic) (e.g., *kukka* 'dog') or derived (e.g., *donga* 'thief' > *donga-tanam* 'theft'; *moga-* 'male' > *moga-tanam* 'manliness'; *cuṭ-ṭam* 'a relative' > *cuṭṭa-rikam* 'relationship'; *andam* 'beauty' > *anda-gatte* 'beautiful woman'; *tiṇḍi* 'eating'> *tiṇḍi-pōtu* 'glutton'; *jūdam* 'gambling'> *jūdari* 'gambler'). Verbs can give rise to two types of derived nouns: action nominals (e.g., *mūyu* 'to close, cover'> *mūy-aḍam* 'closing, covering'; *pilucu* 'to call'> *pilawa-ḍam* 'calling') or substantive nominals (*mūyu* 'to close, cover'> *mū-ta* 'a cover, lid'; *pilucu* 'to call'> *pilu-pu* 'invitation').

Table 2 Vowels

	FU	*CU*	*BR*
High	i ī		u ū
Mid	e ē		o ō
Low		a ā	

Number

A simple or derived noun can be inflected for plural number by the addition of a plural suffix. The plural suffix has two morphophonemic alternants: *-lu* and *-ḷu*. [e.g., 'dog': *kukka* (sg.), *kukka-lu* (pl.); 'backyard': *peraḍu* (sg.), *peraüu* (pl.); 'cat': *pilli* (sg.), *pillulu* (pl.); 'house': *illu* (sg.), *iḷḷu* (pl.); 'eye': *kannu* (sg.), *kaḷḷu* (pl.)]. Some nouns require their oblique stems to receive the plural suffix [e.g., 'pit': *goyyi/gōyi* (sg.), *gōtu-lu* (pl.); 'horse': *gurram* (sg.), *gurrā-lu* (pl.)].

Case

The direct stem of a singular or a plural noun functions as a noun in nominative case. Other case forms of nouns are obtained by means of several case suffixes and postpositions. Some of them are accusative *-ni/-nu*; dative *-ki/-ku*; instrumental/sociative: *-tō*; ablative *-nunci*; comparative *-kaṇṭe*; and locative *-lō*. The oblique stem of a noun functions as its genitive form (e.g., *nā* 'my', *rāti* 'of stone' [*rāyi* 'stone']). A few postpositions are: *kinda* 'below,' *mīda* 'above,' *lōpala* 'inside,' *mundu* 'in front of, before,' *tarawāta* 'after.'

Numerals

Structure of the numerals follows the general Dravidian pattern. Cardinal numerals 1000, 100, and 1 to 10 are mono-morphemic. They are: *okaṭi* '1,' *reṇḍu* '2,' *mūḍu* '3,' *nālugu* '4,' *aidu* '5,' *āru* '6,' *ēḍu* '7,' *enimidi* '8,' *tommidi* '9,' *padí* '10,' *nūru/wanda* '100,' and *vēyi/veyyi* '1000.' The formula for forming decades is: 2, 3 and so on, followed by 10 (e.g., *nalabhai* [4–10] '40'). The formula for series between decades (e.g., 41–49) is: numeral for decade followed by 1–9 (e.g., *nala-bhai-reṇḍu* [4-10-2] 'forty-two'). Ordinals are derived from cardinals by suffixation of *-awa* (> *ō*) (e.g., *āru-awa* > *ārawa/ārō* 'sixth').

Adjectives and Adverbs

Adjectival forms that function solely as modifiers of nouns or other adjectives (and nothing else) are very few in the language; for example, *ara* 'half,' *pāwu* 'a

quarter,' *ceri* 'each.' These adjectives can be followed only by a noun. The demonstrative and interrogative roots: *ā* 'that,' *ī* 'this,' *ē* 'which,' are also adjectives. They are used before nouns (e.g., *ā pilla* 'that girl', *ē pilla* 'which girl'). Their variants can take various suffixes to give rise to different forms (e.g., *akkaḍa* 'there,' *appuḍu* 'then,' *aṭu* 'that side,' *alāga* 'in that manner,' *awatala* 'on that side,' *anni* 'that many,' *anta* 'that much'). Even the third-person pronouns can be viewed as derivatives of these forms.

Some adjectives are bound and require a suffix or a noun to follow it (e.g., *tella* 'white': *tella-wāḍu* 'white man,' *tella-ni/-ṭi maniṣi*' 'white person,' *tella-gā* 'whitish,' *tella-na* 'whiteness'). A large number of adjectives are derived from other forms such as nouns, adverbs, and verbs. A noun in genitive case always functions as an adjective (e.g., *nā pustakam* 'my book,' *rāti gōḍa* 'stone wall'). Some examples of adjectives derived from adverbs are: *alāṭi maniṣi* 'a person of that type' [*alā(ga)* 'in that manner']; *rēpaṭi pani* 'work of tomorrow' (*rēpu* 'tomorrow'). A majority of nouns function as modifiers when placed before another noun (e.g., *goppa maniṣi* 'great man').

It is difficult to find monomorphemic adverbs. Even the adverbs of time and place such as *ninna* 'yesterday,' *appuḍu* 'then,' are either basically nominals or are derived from adjectival roots. The main adverb deriving suffix is *-gā*, as in *gaṭṭi-gā* 'hard.' Many onomatopoeic words are basically adverbial in function (e.g., *gaba-gabā* 'quickly').

Verb

Like in many other Dravidian languages, verb in this language has the most complex structure. A fully inflected verb contains a verb stem followed by optional suffixes. The stem is simple, derived, or compound. A simple stem is composed of one verb root (e.g., *caccu* 'to die'). A derived stem contains a verbal or nominal root followed by a derivative suffix (e.g., *cam-pu* 'to kill', *cam-pincu* 'to cause to kill'); *ūh-incu* 'to imagine' (from *ūha* 'imagination'). A compound verb stem contains a main verb followed by one or more auxiliary verbs (e.g., *waṇḍu-konu* 'to cook for oneself' [*waṇḍu* 'to cook'], *waṇḍu-kona-bōwu* 'to be about to cook for oneself').

A verb stem is inflected for tense/mode, which takes a further pronominal suffix (in the case of finite verbs). Most of the inflectional suffixes have two or more allomorphs. Some of the finite tense/mode forms are – Imperative: *tinu [<tinu-u]* '(You sg.) eat!' *tinaṇḍi [<tinu-aṇḍi]* '(You pl.) eat!' Negative imperative: *tinaku [<tinu-aku]* >'(You sg.) don't eat!' *tinakaṇḍi [<tinu-aku-aṇḍi]* >'(You pl.) don't eat!' Past: *pilicēnu [<pilucu-ē-nu]* 'I called'; *pilicindi [<pilucu-in-di]* 'It called.' Nonpast/Habitual: *tiṇṭāḍu [<tinu-ṭā-ḍu]* 'He will eat/He eats'; *tiṇṭāmu [<tinu-ṭā-mu]* 'We will eat/We eat.' Durative: *tiṇṭunnādu [<tinu-ṭunnā-ḍu]* 'He is/was eating'. Nonpast Negative: *tinanu [tinu-a-nu]* 'I will not eat'; *pilawaḍu [<pilucu-a-ḍu]* 'He will not call'. Hortative: *tindām [tinu-dā-mu]* 'Let us eat!' Sample paradigms of three regular tenses inflected for all the persons (for the verb *tinu* 'to eat') follow:

	Past	*Nonpast*	*Nonpast Negative*
1s	tinnānu	tiṇṭānu	tinanu
1e-pl/ 1i-pl	tinnāmu	tiṇṭāmu	tinamu
2s	tinnāwu	tiṇṭāwu	tinawu
2pl	tinnāru	tiṇṭāru	tinaru
3s-mh	tinnāḍu	tiṇṭāḍu	tinaḍu
3s-nmh	tinnādi> tinnadi>tindi	tiṇṭundi	tinadu
3pl-h	tinnāru	tiṇṭāru	tinaru
3pl-nh	tinnāyi	tiṇṭāyı	tinawu

Nonfinite verbs do not terminate in a Pronominal suffix. They form nonfinite or subordinate clauses in a sentence. The resulting forms have adverbial, adjectival, or nominal functions. Some of the nonfinite forms are obtained by a single suffix such as: Perfective (e.g., *cadiw-i* 'having read'), Negative Perfective: *cadaw-aka* 'not having read'; Durative: *caduwu-tū* 'while reading'; Conditional: *cadiw-itē* 'if one reads'; Concessive: *cadiw-inā* 'even if one reads.' Some Nonfinite forms are obtained by adding more than one suffix or auxiliary (e.g., *cadaw-aka-pō-tē* 'if one does

Table 3 Third-person pronouns

pl-nh	aw1	wāṭi	iwi	wīṭi	ēwi	wēṭḷ

not read'). Relative participle forms are adjectival in function – they are: Past: *cadiw-ina* 'one who read, one which was read'; Nonpast: *cadiw-ē* 'one who reads, one which is/will be read'; Negative: *cadaw-ani* 'one who does/did not read, one which is/was not read.' The other important nonfinite forms are Verbal noun (e.g., *cadawaḍam* 'reading'), and Infinitive which forms the basis for many further expansions (e.g., *cadawa*, as in *cadawa-kūḍadu* 'one should not read').

Verbs are classified into different conjugation classes that account for the various morphophonemic changes that they undergo during the process of inflection.

An extensive process of verbal compounding gives rise to forms expressing different kinds of modes. These compound verbs can be classified on the basis of the inflected form of the nuclear verb. Some examples follow. *With infinitive as the nucleus*: Permissive: *cadawa-waccu* 'one may read'; Inceptive: *cadawa-bōyēnu* 'I was about to read'; Potential: *cadawa-gala-nu* 'I can read'; Negative Potential: *cadawa-lē-nu* 'I cannot read'; Negative Past: *cadawa-lēdu* 'One did not read'; Obligative: *cadaw-āli* 'One should read'; Negative Injunctive: *cadawa-kūḍadu* 'One should not read'; Prohibitive: *cadawa-waddu* 'Don't read.' *With past participle as the nucleus*: Benefactive: *cadiwi-peṭṭ-ēnu* 'I read it (for somebody)'; Decisive: *cadiwi-tīru-tānu* 'I will definitely read'; Completive: *cadiwi-wēs-ēnu* 'I finished reading.'

Syntax

Telugu is an SOV language. "It is a nominative-accusative language and hence, the verb agrees with the argument in the nominative case. It has postpositions and the genitive precedes the governing noun. The comparative marker follows the standard of comparison. The complementizer occurs in the right peripheral position. Adjectives and participial adjectives precede the head noun. There are no pleonastic or expletive constructions such as *it* or *there*. It is a pro-drop language. The subject, direct object, indirect object, and adverbial phrase of the finite embedded and matrix sentence may be pro-dropped. There occur clefts in Telugu and the clefted constituent occurs as the rightmost element just as in other Dravidian, Tibeto-Burman languages and Sinhalese" (Subbarao and Bhaskararao, 2004: 161). It has four kinds of nonnominative constructions and different types of verb-less sentences.

Vocabulary

Like many other Dravidian languages, the vocabulary of Telugu contains native Dravidian as well as borrowed vocabulary. The earliest borrowings were mostly from Sanskrit and Prakrit. Some of the borrowings were assimilated to fit the native phonology. Later borrowings came from Perso–Arabic sources through Urdu, Portuguese, and English in that order. Except for the sound [*f*] all the other sounds of the borrowed sources that are not native to Telugu were replaced by nearer native sounds. Because verbal vocabulary is more resistant to accepting borrowals, although borrowing verbal concepts, the corresponding nouns from the source language were borrowed, which were verbalized by means of suffixation (e.g., *ūhincu* 'to imagine' [Sanskrit *ūha* 'imagination'], *ānandincu* 'to enjoy' [Sanskrit *ānanda* 'happiness' or by means of verbal conjuncts (e.g., *ḍraywu-cēyu* 'to drive' [English *drive*]; *pūja-cēyu* 'to worship' [Sanskrit *pūjā* 'workship']).

Template Morphology

G T Stump, University of Kentucky, Lexington, KY, USA

© 2006 Elsevier Ltd. All rights reserved.

In complex inflectional systems, the morphology of an inflected word may involve more than one affix. In such instances, the sequence of affixes is sometimes variable. For instance, Luutonen (1997: 13) cited the example in (1) as one instance of variable affix order in Mari.

(1) Mari (Uralic)
a. joltaš-em-βlak
friend-my-PL
'my friends'
b. joltaš-βlak-em
friend-PL-*my*
'my friends'

Cross-linguistically, however, instances of this sort are comparatively rare: ordinarily, affix order is invariant. In the Southeastern Tepehuan (Tepehuán Sureste) verb form in (2), for example, the ordering of affixes is fixed.

(2) Southeastern Tepehuan (Tepehuán Sureste) (Uto-Aztecan)
mu-va-tu-vai'
REMOTE.LOCATION-REALIZATION.ASPECT-EXTENT.ASPECT-*drew.water*
'there he then drew water' (Willett, 1991: 46)

In instances of fixed affix ordering, it is natural to ask why the affixes must appear in the observed order. The simplest (and least satisfying) answer is that they just do – that the ordering doesn't follow from any general set of principles, but is simply stipulated by the morphology of the language in question. Template morphology is the name given to affixal morphology whose ordering is assumed to be stipulated in this way.

Southeastern Tepehuan (Tepehuán Sureste) provides a good example of template morphology. Verbal affixes in Southeastern Tepehuan (Tepehuán Sureste) fall into five prefixal and eight suffixal classes, as schematized in Figure 1. In the syntagmatic dimension, the affixes in a given class are rigidly ordered relative to the affixes in every other class; in the paradigmatic dimension, affixes in the same class are mutually exclusive. Affix classes possessing these properties are called position classes. The prefix position classes of Southeastern Tepehuan (Tepehuán Sureste) are given in Table 1: affixes listed in the same box belong to the same position class, and are therefore paradigmatically opposed to each other; the affixes in a given box may combine, in the indicated order, with semantically compatible affixes in the boxes to its right or left. Some affix classes have the special property that they span two or more prefix positions – that is, their members are paradigmatically opposed to any combination of affixes occupying those positions; Stump (2001) discussed these as portmanteau position classes.

Prefix positions					Verb stem	Suffix positions							
5	4	3	2	1		1	2	3	4	5	6	7	8

Figure 1 Southeastern Tepehuan position classes.

Because labeling a system of affixal morphology as templatic implies that there is no independent explanation for the ordering of its affixes, much of the research on systems that have been so labeled is devoted precisely to showing that they are not actually templatic. Bybee (1985) investigated the hypothesis that a verb's affixes are sequenced according to their degree of semantic relevance to the verb, where an inflectional category "is *relevant* to the verb to the extent that *the meaning of the category directly affects the lexical content of the verb stem*" (Bybee, 1985: 15); comparing systems of verb inflection in a 50-language sample, she found a strong positive correlation between a verbal affix's relative proximity to the verb stem and its degree of semantic relevance to the verb. More recently, Rice (2000) presented extensive evidence that Athapaskan verb morphology (long cherished as a textbook example of templatic morphology) is not in fact templatic, but instead exhibits semantically motivated affix ordering. (See McDonough, 2000 for additional arguments against a templatic analysis of Athabaskan verb morphology.)

Not all systems of affix ordering admit such independent explanations, however. Thus, two languages may contrast with respect to their ordering of affixal exponents of the same morphosyntactic properties; for instance, the voice suffix *-he* precedes the tense suffix *-sh* in Albanian *lahesha* 'I was washed,' while the exponent of tense precedes that of voice in Latin *lavābar* 'I was washed' (Stump, 2001: 25). Moreover, a single language may exhibit contrasting affix ordering in different morphosyntactic contexts. In the inflection of Fula verbs, for instance, the first-person singular subject suffix *-mi* appears before an accompanying object suffix in some instances but after it in others, depending on the object's person and number, as the examples in (3) illustrate. Evidence of this kind suggests that at least some morphology must be acknowledged to be templatic. (See Hyman, 2003 for arguments to this effect from the Bantu languages; see Good, 2003 for evidence that templatic structures exist in the domain of syntax as well as morphology.) In addition, languages sometimes place

syntagmatically similar affixes into paradigmatic opposition even though there is no logical incompatibility between them; for instance, there is no reason why the notions of distal location and repetition should be mutually exclusive in their morphological expression in Southeastern Tepehuan (Tepehuán Sureste); the fact that they are can only be attributed to the sort of stipulation embodied by Table 1.

(3) Gombe Fula (Niger-Congo)
  a. mball-u-mi-ɓe'
     help-RELATIVE.PAST.ACT-1SG-3PL.CLASS.2
     'I helped them'
  b. mball-u-maa-mi'
     help-RELATIVE.PAST.ACT-2SG-1SG
     'I helped you (sg.)'
  c. mball-u-moo-mi'
     help-RELATIVE.PAST.ACT-3SG.CLASS.1-1SG
     'I helped him' (Arnott, 1970: Appendix 15)

Template morphology is sometimes contrasted with layered morphology, in which the ordering of affixes is intrinsic. An instance of layered morphology is that of the English word *patronizingly*, in which the ordering of the suffixes *-ize*, *-ing*, and *-ly* is necessitated by the fact that of the three affixes, only *-ize* combines with *patron* (though *patronly* is marginally possible with a different suffix *-ly*) and that of *-ing* and-*ly*, only the former combines with *patronize* (though *-ly* combines with *patronizing*).

Simpson and Withgott (1986) identified six criteria for distinguishing template morphology from layered morphology; these are summarized in Table 2. According to criterion (a), the absence of any marking may be used to signal some property or set of properties in a system of template morphology. (Because the substance of this criterion in no way depends upon the postulation of 'zero morphemes,' I opt here for more theory-neutral terminology than is used by Simpson and Withgott.) Thus, in Southeastern Tepehuan (Tepehuán Sureste), the absence of any affix in prefix position 1 (Table 1) may signal the property set 'third person singular object': the absence of any marking in this position is precisely what distinguishes the form of a transitive verb having a third-singular object from forms of the same verb having some other sort of object. Layered morphology does not involve significative absence of this sort. For instance, there is no derivative of the noun *friend* whose contrast with other derivatives (e.g., *friendship*, *friendly*, *friendless*) is signaled by its lack of any overt mark of derivation. There are, of course, instances of zero derivation in English, but the absence of derivational marking in such forms is not obviously significative: the status of the noun *cook* as a nominal derivative of the verb *cook* isn't signaled by its lack of any derivational marking, but by its nominal morphosyntax (e.g., *the cooks left*), its phonological identity to the verb *cook*, and the fact that its meaning is built on that of *cook*. Indeed, Simpson and Withgott regard zero derivation as a characteristic of layered rather than template morphology (criterion [b]) because the effects of zero derivation very often parallel those associated with overt affixes in systems of layered morphology; for instance, the derivation of *cook* (n.) from *cook* (v.) parallels the derivation of agent nouns in *-er* (e.g. *bake* → *baker*) – which, by other criteria, is an instance of layered morphology.

According to criterion (c), the combination of an affix with a stem exhibits monodeterminacy in the case of layered morphology, but not in the case of template morphology. In instances of monodeterminacy, the morphosyntactic properties of a stem + affix combination are determined (in some sense) by only one of its parts – either the stem or the affix. (Because

the substance of this criterion in no way depends upon the potentially controversial conception of headedness assumed by Simpson and Withgott, I opt here for more theory-neutral terminology.) By this criterion, the combinations *super-sonic* and *bak-er* both involve layered morphology: in both instances, the syntactic category of the combination is determined by one of its parts (*-sonic* and *-er*, respectively). By contrast, a Southeastern Tepehuan (Tepehuán Sureste) verb exhibits polydeterminacy: its morphosyntactic properties cannot be deduced from any single part, but only from the sum of its parts.

By criterion (d), layered morphology is subject to the adjacency constraint (Allen, 1978; Siegel, 1978), but template morphology is not. According to this constraint, the addition of an affix to a stem is insensitive to all but the stem's outermost layer of structure. Thus, the formation of an abstract noun from an adjective may be sensitive to the adjective's outermost affix: adjectives give rise to abstract nouns by means of a variety of derivational affixes (*real-ity*, *shy-ness*, *tru-th*), but adjectives having *-al* in their outermost layer of morphology generally require the use of *-ity* (*musicality*, *conviviality*, *actuality*). On the other hand, the choice of noun-deriving suffix is never sensitive to any more internal part of an adjective's morphology; for instance, the fact that *intentional* derives ultimately from a verb (*intend*) is just irrelevant to the choice of morphology for its nominal derivative. In instances of template morphology, by contrast, the addition of an affix sometimes seems to be sensitive to the internal morphology of the stem with which it joins. In the Fula verb forms in (4), for example, both the subject agreement prefix and the object agreement suffix are sensitive to the tense expressed on the verb's stem (i.e., to the first continuous in [4a] and the general future in [4b]); yet the principal exponent of tense in the stems with which these affixes join is not in their outermost layer of structure, in apparent violation of the adjacency constraint.

(4) Fula (Niger-Congo)
  a. 'odɔ̀n-wall-u-no-maa'
     3SG.SUBJ-*help*-FIRST.CONTINUOUS-PRETERITE-2SG.OBJ
     'he was helping you'
  b. 'o-wall-ay-no-ma
     3SG.SUBJ-*help*-GENERAL.FUT-PRETERITE-2SG.OBJ
     'he was going to help you'
     (Arnott, 1970: Appendix 15)

While the adjacency constraint limits an affix's sensitivity to the internal structure of the stems with which it joins, the no-lookahead constraint excludes the possibility that an affix appearing in some word might be sensitive to more peripheral parts of that word's morphological structure. For example, this constraint excludes the possibility that the derivation of an inchoative verb stem from an adjective might involve the suffix *-ize* if that verb stem itself subsequently underwent nominal derivation, but otherwise the suffix *-en*. In instances of template morphology, by contrast, the appearance of an affix in a word is sometimes apparently conditioned by that word's more peripheral morphology (criterion [e]). Thus, in the Fula verb forms in (5), the suffix of the relative future active appears as *-ay* or *-at* depending on the subject agreement properties expressed by the following suffix.

(5) Fula (Niger-Congo)
  a. loot-ay-mi
     wash-RELATIVE.FUT.ACT-1SG.SUBJ
     'I will wash'
  b. loot-at-aa
     wash-RELATIVE.FUT.ACT-2SG.SUBJ
     'you will wash' (Arnott, 1970: 202)

It should be noted, however, that the claim that template morphology violates the adjacency and no-lookahead constraints is only meaningful in the context of a morpheme-based conception of morphology. In a realizational theory of morphology (see Stump, 2001 and references cited there), neither the agreement alternations in (4) nor the tense–affix alternation in (5) is conditioned by a verb's morphological structure; rather, they are conditioned by the morphosyntactic property set with which a verb is associated independently of its structure.

Simpson and Withgott's final criterion relates to the fact that systems of template morphology often allow a predicate to encode more than one of its arguments; for instance, the systems of verb inflection in Southeastern Tepehuan (Tepehuán Sureste) and

Table 2 Criteria for distinguishing between layered and template morphology

	Layered morphology	*Template morphology*
a. Zero morphemes [i.e., significative absence]	No	Yes
b. Zero derivation	Yes [?]	No [?]
c. Contains one root, one head [i.e., monodeterminacy]	Yes	No
d. Adjacency constraint	Yes	No
e. No-lookahead constraint	Yes	No
f. Usually encodes at most one argument	Yes	No

Reprinted, with kind permission of Kluwer Academic Publishers, from Stump (1997: 218), example (3), © 1997 Kluwer Academic Publishers; reprinted in modified form from Simpson and Withgott (1986: 156), © 1986, with permission from Elsevier.

Fula exhibit both subject and object agreement. Simpson and Withgott's inclusion of criterion (f) implies that some agreement systems are layered. But this raises a more general question: how does the distinction between template and layered morphology relate to the distinction between inflection and derivation? Stump (1997) examined this issue, and concluded that derivation is sometimes layered and sometimes templatic, but that by Simpson and Withgott's criteria, inflection is generally templatic (even if its status as such is inevitably obscured in languages which exhibit fairly little inflectional morphology).

Another important question relating to template morphology concerns the manner in which templatic stipulations on a language's morphology should be represented formally. The unfortunate choice of the template metaphor prejudices the issue in favor of the conclusion that these stipulations take the form of positive output constraints. No one, however, has proposed a theory of inflectional morphology which develops this conclusion with sufficient formal rigor to allow it to be evaluated objectively; such a theory would, in any event, be entirely *ad hoc* in its treatment of templatic stipulations. Another proposal which has enjoyed some favor is that inflectional affixes are functional heads in syntax, so that the ordering of affixes reflects the nesting of functional categories in syntax; this approach is, however, at odds with the widespread existence of language-specific idiosyncrasies of affix ordering for which the corresponding nesting of functional categories lacks any independent syntactic motivation. Another proposal for the representation of templatic stipulations is to equate these with the ordering restrictions implicit in the definition of a language's paradigm function. This is a more satisfactory approach, because the postulation of paradigm functions is independently motivated (Stump, 1997; Stump, 2001); moreover, it directly accommodates a range of otherwise recalcitrant position class phenomena (Stump, 1993), including portmanteau position classes as well as ambifixal position classes (in which prefixes and suffixes are paradigmatically opposed to one another), parallel position classes (whose member affixes are available to more than one affix position in a word's structure), and reversible position classes (whose ordering varies according to the morphosyntactic property set being realized).

Temporal Logic

Tense Logic

Tense Logic was introduced by Arthur Prior (1957, 1967) as an aid to elucidating various philosophical problems concerning time. Because it was used to provide formal renderings of propositions originally formulated as natural language sentences, it was natural to consider Tense Logic also as a tool for linguistic analysis in the context of linguistics rather than philosophy. As such, it was soon found to have considerable limitations, which stimulated the development of extensions or alternatives to Tense Logic as it had been conceived originally by Prior.

Syntax of Priorean Tense Logic

Prior took the basic expressions of temporality in ordinary language to be the past, present, and future tenses. For the past and the future, he introduced proposition-forming operators P and F, called **tense operators,** which, when prefixed to any proposition ϕ, yielded propositions that expressed, respectively, the past-tense and future-tense versions of ϕ, for example:

ϕ: It is raining.
$P\phi$: It was raining.
$F\phi$: It will be raining.

(More often, in fact, Prior would render $P\phi$ in the form 'It has been raining', using the present perfect rather than the simple past. In English, this reads more naturally because 'It was raining' seems to refer implicitly to some particular time assumed known.)

Used in combination with the standard connectives of Propositional Logic ($\wedge$, $\vee$, $\rightarrow$, $\leftrightarrow$, $\neg$), Prior's tense operators allowed one to express temporal relationships, e.g., using ϕ for 'John arrives' and ψ for 'Mary leaves',

$P(\phi \wedge \psi)$: John arrived when Mary left.
$P(\phi \wedge P\psi)$: When John arrived, Mary had left.
$F(\phi \wedge P\psi)$: When John arrives, Mary will have left.

This kind of analysis is too crude to capture the nuances of expression possible in natural language. Whereas the formulae $P(\phi \wedge \psi)$ and $P(\psi \wedge \phi)$ are logically equivalent, the sentences 'John arrived when Mary left' and 'Mary left when John arrived' are not. It might be argued, however, that the two sentences share some 'core' semantic content, and that this is what is expressed by the logical formulae. On this basis, Tense Logic is worth studying for the clarity it affords in analyzing at least some aspects of the linguistic expression of time.

Of particular interest is the interaction of the tense operators with negation. The formula $\neg P\phi$ says it has never been true that ϕ; it is not equivalent to $P\neg\phi$, which merely says it has (at least once) been false that ϕ. Reading ϕ as 'The prime minister of the UK is a woman', $\neg P\phi$ is false (because of Margaret Thatcher), whereas $P\neg\phi$ is true (because of all the other prime ministers). The negation of the latter, $\neg P\neg\phi$, says it has never been false that ϕ, and hence that ϕ has always been true. Prior introduced a new operator, H, as an abbreviation for the sequence $\neg P\neg$, and analogously G for $\neg F\neg$. The full set of operators is now

$P\,\phi$: It has been the case that ϕ (on at least one occasion).
$H\phi$: It has always been the case that ϕ.
$F\,\phi$: It will be the case that ϕ (on at least one occasion).
$G\phi$: It will always be the case that ϕ.

Using these, Prior could enunciate tense-logical theses such as $\phi \rightarrow GP\phi$, which says that if ϕ is true now then it will always be the case that ϕ *has* been true.

Semantics of Tense Logic

To express the meaning of the tense operators, we assume that propositions are evaluated as true and false at times, that a proposition may be true at some times and false at others, and that times are ordered by the relations *earlier than* and *later than*:

$P\,\phi$ is true at time t if and only if ϕ is true at some time t' earlier than t.
$H\,\phi$ is true at time t if and only if ϕ is true at every time t' earlier than t.
$F\,\phi$ is true at time t if and only if ϕ is true at some time t' later than t.
$G\,\phi$ is true at time t if and only if ϕ is true at every time t' later than t.

In the standard formal semantics for Tense Logic, a temporal frame is a pair $(T, \prec)$, where T is a set of times, and $\prec$ is a binary relation on T. For $t, t' \in T$, we understand $t \prec t'$ as the formal counterpart of the relation 't is earlier than t''. An interpretation $\mathcal{I}$ over frame $\mathcal{F} = (T, \prec)$ assigns a truth value to each atomic formula at each time in the frame. The fundamental semantic relation is satisfaction of formula ϕ at time t in frame $\mathcal{F}$ under interpretation $\mathcal{I}$, symbolized as $\mathcal{F}, t \models_{\mathcal{I}} \phi$. If this does not hold, we write $\mathcal{F}, t \not\models_{\mathcal{I}} \phi$.

We assume that all such relations are known for each *atomic* formula at each time; the truth values of compound formulae are determined by the semantic rules:

$\mathcal{F}, t \models_{\mathcal{I}} P\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for some $t' \in T$ such that $t' \prec t$.
$\mathcal{F}, t \models_{\mathcal{I}} H\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for every $t' \in T$ such that $t' \prec t$.
$\mathcal{F}, t \models_{\mathcal{I}} F\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for some $t' \in T$ such that $t \prec t'$.
$\mathcal{F}, t \models_{\mathcal{I}} G\phi$ if and only if $\mathcal{F}, t' \models_{\mathcal{I}} \phi$ for every $t' \in T$ such that $t \prec t'$.

(For Boolean compounds with $\wedge$, $\vee$, etc., the standard rules are used.)

Some tense-logical formulae can now be proved to be universally valid, i.e., satisfied at every time in every frame. An example is Prior's formula $\phi \rightarrow GP\phi$. For suppose $\mathcal{F}, t \models_{\mathcal{I}} \phi$, and let $t' \in T$ be any time such that $t \prec t'$. Then the semantic rule for P implies $\mathcal{F}, t' \models_{\mathcal{I}} P\phi$. Because this holds for every $t' \in T$ such that $t \prec t'$, the rule for G gives us $\mathcal{F}, t \models_{\mathcal{I}} GP\phi$, as required. The formulae provable in this way constitute a system known as Minimal Tense Logic, generally designated K_t.

Because the class of all temporal frames imposes no constraints on the nature of the $\prec$ relation, K_t does not provide an adequate basis for reasoning about temporal relationships. It is therefore usual to restrict the class of frames by requiring $\prec$ to satisfy certain structural properties such as transitivity, density, or linearity. A transitive frame $(T, \prec)$, for example, obeys the rule

TRANS $\forall t, t', t'' \in T\ (t \prec t' \wedge t' \prec t'' \rightarrow t \prec t'')$

i.e., if t is earlier than t', which in turn is earlier than t'', then t must be earlier than t''. It can be shown that TRANS *characterizes* transitive frames in the following sense:

The frame $\mathcal{F} = (T, \prec)$ is transitive if and only if $\mathcal{F}, t \models_{\mathcal{I}}$ TRANS for every interpretation $\mathcal{I}$ over $\mathcal{F}$, and every time $t \in T$.

Much attention has been given to the problem of finding tense-logical formulae which correspond to first-order frame properties just as TRANS corresponds to transitivity (Van Benthem, 1991). Not all frame properties have corresponding tense-logical formulae, and conversely, not all tense-logical formulae correspond to first-order frame properties. Thus, there is no first-order characterization of the frames for which $GF\phi \rightarrow FG\phi$ holds; and no tense-logical formula exactly characterizes the *irreflexive* frames, which satisfy $\forall t\ \neg(t \prec t)$.

Extensions of Tense Logic

Increasing the Expressive Power: 'Since' and 'Until'

Sentences such as *John has been happy since Mary arrived* and *John will be happy until Mary arrives* cannot be expressed using Prior's operators. In 1968, Hans Kamp introduced binary operators S and U with the following semantics:

$\mathcal{F}, t \models_{\mathcal{I}} S\phi\psi$ if and only if there is a time $t' \prec t$ such that
(i) $\mathcal{F}, t' \models \phi$, and
(ii) $\mathcal{F}, t'' \models \psi$ for every $t'' \in T$ such that $t' \prec t'' \prec t$.
$\mathcal{F}, t \models_{\mathcal{I}} U\phi\psi$ if and only if there is a time $t' \prec t$ such that
(i) $\mathcal{F}, t' \models \phi$, and
(ii) $\mathcal{F}, t'' \models \psi$ for every $t'' \in T$ such that $t \prec t'' \prec t'$.

Let ϕ stand for 'Mary arrives' and ψ for 'John is happy'. Then $S\phi\psi$ is true now so long as Mary arrived at some past time, and John was happy at every time between then and now – in other words, John has been happy since Mary arrived. Similarly, $U\phi\psi$ is true now if Mary will arrive at some future time, and John will be happy at every time between now and then. This implies John will be happy until Mary arrives, but is not equivalent to it, because the English sentence would also be true if Mary never arrives, so long as John remains happy forever. This can be expressed as $U\phi\psi \vee G\psi$.

Kamp showed that for frames in which the flow of time is ordered like either real numbers or integers, the operators S and U suffice to express every first-order property expressible by means of $\prec$ and quantification over times. In this sense, the logic of S and U is *expressively complete* in a way that the logic of P, F, G, and H is not.

The Indeterminate Future

Although it is natural to suppose that a temporal frame should be linear, the need has frequently been felt for temporal frames with a branching structure. In a linear frame, given two distinct times, one must precede the other: $\forall t, t' \in T(t = t' \vee t \prec t' \vee t' \prec t)$. The most popular form of non-linear structure is a *future-branching* frame, in which each time has a unique linear past, but may have many distinct futures. This is secured by the 'left-linearity' axiom that restricts linearity to times in the past of a given time: $\forall t, t', t''\ (t \prec t'' \wedge t' \prec t'' \rightarrow t = t' \vee t \prec t' \vee t' \prec t)$.

This kind of structure supports reasoning about alternative *possible futures*: it captures the idea that whereas the past is fixed, the future is indeterminate. This means that some future events are inevitable

(occurring in every possible future) whereas others are merely possible (occurring in some but not all possible futures). To quantify possible futures, we introduce modal operators. One way of doing this is as follows: $\Diamond\phi$ says there is a possible future which makes ϕ true now (so ϕ is possible), while $\Box\phi$ says that every possible future makes ϕ true now (so ϕ is necessary). The semantics makes explicit reference to possible futures; a *history* is any maximal linear subset of T, and formulae are evaluated with respect to pairs (H, t), where H is a history and $t \in H$. Semantic rules for the existing operators can be straightforwardly rewritten by incorporating a single history term, as e.g.,

$\mathcal{F}, H, t \models_{\mathcal{I}} F\phi$ if and only if $\mathcal{F}, H, t' \models_{\mathcal{I}} \phi$ for some $t' \in H$ such that $t \prec t'$.

For the new modal operators, we have the rules

$\mathcal{F}, H, t \models_{\mathcal{I}} \Diamond\phi$ if and only if $\mathcal{F}, H', t \models_{\mathcal{I}} \phi$ for some history H' such that $t \in H'$
$\mathcal{F}, H, t \models_{\mathcal{I}} \Box\phi$ if and only if $\mathcal{F}, H', t \models_{\mathcal{I}} \phi$ for every history H' such that $t \in H'$

In these rules, because t is in both H and H', and branching is only into the future, these histories must coincide at least up to t. We can now interpret compound formulae such as

$\Diamond F\phi$	ϕ will be true in some possible future.
$\Box F\phi$	ϕ will be true in every possible future.
$P\Box F\phi$	It was inevitable that ϕ would eventually be true.

Interval Semantics

In the standard semantics for Tense Logic, the elements of a temporal frame are instants, that is, temporal elements lacking duration. A further possibility is to use temporal frames containing intervals as well as, or instead of, instants. This approach has been favored by those seeking to give a logical account of aspect in natural language, which requires us to handle events that take time (Dowty, 1979). The statement *John runs a mile* ($=\phi$) reports the occurrence of an event of several minutes' duration. It seems inappropriate to evaluate ϕ at instants, because there is no instant at which John runs a mile. Instead, interval semantics evaluates ϕ as true with respect to any interval i over which John runs a mile. Because running a mile is an accomplishment (Vendler, 1967), this means that ϕ will not be true on any proper subinterval of i—in contrast to the progressive form *John is running a mile*, which would be true.

Formally, we use frames of form $\mathcal{F} = (I, \prec, \sqsubset)$, where I is a set of intervals, $\prec$ is the 'earlier than' relation on intervals, and $\sqsubset$ is the proper subinterval relation. Accomplishments and activities are distinguished by their different entailments: an accomplishment sentence satisfies the rule

(ACC) If $\mathcal{F}, i \models_{\mathcal{I}} \phi$ and $i' \sqsubset i$ then $\mathcal{F}, i' \not\models_{\mathcal{I}} \phi$,

whereas an activity sentence satisfies

(ACT) If $\mathcal{F}, i \models_{\mathcal{I}} \phi$ and $i' \sqsubset i$ then $\mathcal{F}, i' \models_{\mathcal{I}} \phi$.

The progressive aspect might be regarded as an operator *Prog* for (among other things) converting accomplishments into activities. The following semantic rule for *Prog* is plausible:

$\mathcal{F}, i \models_{\mathcal{I}} Prog(\phi)$ if and only if $\mathcal{F}, i' \models_{\mathcal{I}} \phi$ for some i' such that $i \sqsubseteq i'$,

and this rule has the consequence that if ϕ is an accomplishment (as defined by ACC) then $Prog(\phi)$ is indeed an activity (as defined by ACT). Thus, basic Tense Logic can be enhanced to capture some of the complexities of temporality in natural language.

This analysis only covers cases where $Prog(\phi)$ is true by virtue of an eventually completed occurrence of the event expressed by ϕ. By the so-called 'imperfective paradox', the former can be true without the latter ever becoming true (e.g., if John stops running before the mile is completed). This property can be captured by combining interval semantics with branching time. A history is now a maximal linear set of intervals (where linearity of a set of intervals can be defined in terms of $\prec$ and $\sqsubset$). A more accurate rendition of the progressive is now

$\mathcal{F}, H, i \models_{\mathcal{I}} Prog(\phi)$ if and only if $\mathcal{F}, H', i' \models_{\mathcal{I}} \phi$ for some H, i' such that $i \sqsubseteq i' \in H'$.

Because i is in both H and H', and branching is only into the future, H and H' must coincide at least up to the end of i; thereafter they may – but need not – diverge, allowing for the possibility that the completion of ϕ occurs in a different history from the one in which $Prog(\phi)$ is being evaluated.

Other Forms of Temporal Logic

The systems discussed above may be thought of as variants of Prior's basic Tense Logic, expressing temporal properties and relations by means of operators. Alongside these, there has been a tradition of modeling temporal information in first-order logic, using individual terms as explicit bearers of temporal reference. Whereas classically one might write, say, *Asleep(john)* for *John is asleep*, the *Method of Temporal Arguments* writes *Asleep(john, t)* to say that John is asleep at time t. Tenses are paraphrased using constructions that mirror the semantic rules for

tense operators, e.g., $\exists\, t'\ (t' \prec t \wedge Asleep(john, t'))$ says that 'John has been asleep' holds at t. For events that take time, we use interval arguments, e.g., $Run(john, mile, i)$, where s is the interval over which John runs a mile.

A well-known variant of this method, from Donald Davidson (1967), replaces temporal arguments by terms denoting individual events, e.g., $\exists e(Run(john, mile, e)\ t'\ Occurs(e, i))$, which says that some event e is the running of a mile by John and occurs on interval i. An advantage of this is that it allows us to analyze adverbial modifiers by means of additional event predicates linked by logical conjunction, e.g., $\exists e(Run(john, mile, e) \wedge Occurs(e, i) \wedge In(e, field))$.

Davidson's method is sometimes known as 'event-token reification', because the e terms refer to *event tokens*, i.e., individual occurrences. An alternative form of reification, particularly favored in Artificial Intelligence, involves state and event *types* (Allen, 1984). In this method, $run(john, mile)$ is a *term* denoting the event type 'John runs a mile'; an occurrence of this type on interval i is expressed as $Occurs(run(john, mile), i)$. A separate predicate is used for state-types, e.g., $Holds(asleep(john), i)$, meaning that John is asleep *throughout* interval i. An advantage claimed for this style of analysis is that by allowing quantification over types it enables expression of general temporal knowledge concerning, for example, causality, e.g., $\forall e, s, e', d(Cause(e, s, e', d) \wedge Holds(s, t) \wedge Occurs(e, t) \rightarrow Occurs(e', t + d))$. The first conjunct states that events of type e occurring under condition s give rise to events of type e' after a delay of length d.

Tense

C Fabricius-Hansen, Germanistisk Institutt, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Tense is a grammatical category that serves to locate situations in time; it is the basic grammatical category that, together with lexical and other indications of ordering in time, enables the hearer to reconstruct the temporal relation between the speech situation and the situation described in a sentence and to reconstruct the relative order of situations described in a text.

It is important to distinguish among tense forms, the rather abstract grammatical meanings expressed by such forms (semantics of tense), and the actual use and interpretation of tenses in natural discourse (pragmatics of tense).

European languages have more or less elaborate tense systems, whereas many non-European languages lack grammatical tense. In languages without tense, temporal ordering is expressed by nongrammaticalized means (e.g., temporal adverbials) alone and the temporal location of the described situation is not necessarily indicated by linguistic means at all.

On Tense Marking

Tense is usually expressed overtly on the (finite) verb by way of morphological markers (cf. *happen-s* vs. *happen-ed, sing* vs. *sang*) or specific auxiliary words (*will happen, has happened, had happened*), depending on typological properties of the individual language. Auxiliaries in their turn are often functionally specialized tense-carrying verbs (cf. *has, had*) governing a nonfinite (e.g., infinitival or participial) form of

tense operators, e.g., $\exists\, t'\ (t' \prec t \wedge Asleep(john, t'))$ says that 'John has been asleep' holds at t. For events that take time, we use interval arguments, e.g., $Run(john, mile, i)$, where s is the interval over which John runs a mile.

A well-known variant of this method, from Donald Davidson (1967), replaces temporal arguments by terms denoting individual events, e.g., $\exists e(Run(john, mile, e)\ t'\ Occurs(e, i))$, which says that some event e is the running of a mile by John and occurs on interval i. An advantage of this is that it allows us to analyze adverbial modifiers by means of additional event predicates linked by logical conjunction, e.g., $\exists e(Run(john, mile, e) \wedge Occurs(e, i) \wedge In(e, field))$.

Davidson's method is sometimes known as 'event-token reification', because the e terms refer to *event tokens*, i.e., individual occurrences. An alternative form of reification, particularly favored in Artificial Intelligence, involves state and event *types* (Allen, 1984). In this method, $run(john, mile)$ is a *term* denoting the event type 'John runs a mile'; an occurrence of this type on interval i is expressed as $Occurs(run(john, mile), i)$. A separate predicate is used for state-types, e.g., $Holds(asleep(john), i)$, meaning that John is asleep *throughout* interval i. An advantage claimed for this style of analysis is that by allowing quantification over types it enables expression of general temporal knowledge concerning, for example, causality, e.g., $\forall e, s, e', d(Cause(e, s, e', d) \wedge Holds(s, t) \wedge Occurs(e, t) \rightarrow Occurs(e', t + d))$. The first conjunct states that events of type e occurring under condition s give rise to events of type e' after a delay of length d.

Tense is a grammatical category that serves to locate situations in time; it is the basic grammatical category that, together with lexical and other indications of ordering in time, enables the hearer to reconstruct the temporal relation between the speech situation and the situation described in a sentence and to reconstruct the relative order of situations described in a text.

It is important to distinguish among tense forms, the rather abstract grammatical meanings expressed by such forms (semantics of tense), and the actual use and interpretation of tenses in natural discourse (pragmatics of tense).

European languages have more or less elaborate tense systems, whereas many non-European languages lack grammatical tense. In languages without tense, temporal ordering is expressed by nongrammaticalized means (e.g., temporal adverbials) alone and the temporal location of the described situation is not necessarily indicated by linguistic means at all.

On Tense Marking

Tense is usually expressed overtly on the (finite) verb by way of morphological markers (cf. *happen-s* vs. *happen-ed, sing* vs. *sang*) or specific auxiliary words (*will happen, has happened, had happened*), depending on typological properties of the individual language. Auxiliaries in their turn are often functionally specialized tense-carrying verbs (cf. *has, had*) governing a nonfinite (e.g., infinitival or participial) form of

the main verb. Combinations of tense auxiliaries and nonfinite main verbs are often termed periphrastic (or compound) tenses, as opposed to nonperiphrastic (one-word) tense forms. Nonfinite verb forms by themselves (e.g., *to happen, happening,* the past participle *happened*) do not encode tenses in the stricter sense of finite tense. Tense languages vary with respect to how many tenses they distinguish formally and how their tenses are organized semantically. In general, tense forms that are unmarked from a formal point of view tend to encode the tense that is least marked from a semantic point of view. Thus, the present tense is zero-marked in most European languages; but in many non-European languages a zero-marked form can express present or past time reference, depending on the type of situation (state or process vs. completed event) described by the tensed verb.

The Semantics of Tense: Basic Principles

From a semantic point of view, tenses are abstract meanings locating the time of the situation or eventuality (action, event, activity, process, or state) described in a sentence – the event (E) or situation time – directly or indirectly with respect to some other time, often termed the reference time or the time of orientation (O). In the default case, it is the time of utterance (U; speech time or speaker's now) that serves as time of orientation. That makes tense an inherently deictic category, anchored in the unique utterance situation (*I*, *here*, *now*).

Often, the term 'absolute' is used for tenses that, in their normal use, are anchored directly in the time of utterance, for example, the present (*happens, is happening*), (simple) past (*happened, was happening*), and future (*will happen, will be happening*) tenses in English. Tenses that, in their normal use, locate the situation time with respect to some time of orientation other than the time of utterance are traditionally called 'relative.' (Relative tenses are discussed later, together with the (present) perfect.) This section is concerned with absolute tense and the principles underlying the meaning of tense in general.

Absolute Tenses (Present, Past, and Future)

There are three basic ordering relations between E and U (or O) to be distinguished, corresponding to the three deictic notions of present, past, and future: The described situation may overlap with the time of utterance, it may precede the time of utterance, or it may be located after the time of utterance. These relations are encoded crosslinguistically by the present (1a), past (1b), and future (1c) tenses, respectively.

(1a) the pope is visiting South America
(1b) the pope visited South America a couple of years ago
(1c) the pope will visit South America next month

These three basic tenses may be represented diagrammatically as in Table 1. The definition of present tense given here, although readily covering such sentences as (1a), might seem less appropriate to (1d) in its most usual interpretation, that is, indicating that Anna has the habit of reading Donald Duck.

(1d) Anna reads Donald Duck

Sentence (1d) can be true even if it is not the case that Anna is reading Donald Duck at the present moment. However, (1d) does not refer to a particular action of reading Donald Duck but rather to a property of Anna, namely that she habitually or regularly reads Donald Duck, and this property is claimed to be true of Anna even at those moments when she is not actually reading Donald Duck. The same applies in the case of sentences such as (1e), with a universal time reference.

(1e) water flows down hill

Note that, the past tense is adequately used in (2a), even though John may still be in the garden at the time of utterance; thus, (2b) is a possible continuation.

(2a) half an our ago, John was in the garden
(2b) in fact, he is still there

That is, E in the formulas for the sentences in (1) (Table 1) does not necessarily represent the time of the situation in its totality. With (atelic) activities, processes, and states (such as 'be in the garden'), the 'real' situation may extend beyond E, which in that case represents just one temporal slice of a larger situation of the same type; compare (2a) and Figure 1. But with (telic) events such as 'leave the house' that are defined by a natural end point, E must include that end point; in this case, then, E does represent the time of a completed situation; compare (2c) and Figure 2.

Table 1 Schematic representations of present, past, and future

Sentence number	*Tense*	*Definition*	*Formalism*[a]
(1a)	Present	Situation time overlaps utterance time	E o U
(1b)	Past	Situation time precedes utterance time	E < U
(1c)	Future	Situation time follows utterance time	E > U

[a]o, overlaps; <, precedes; > follows.

(2c) half an our ago, John left the house

For the reasons mentioned, what absolute tense locates with respect to the utterance time could be conceived as a temporal frame or 'time under consideration' that, in its turn, overlaps with the time of the described situation rather than as the situation time itself. In what follows, then, bear in mind that, depending on the situation type and aspectual properties of the sentence, E may represent a complete situation ('perfective viewpoint') or a situation that is cut from a larger situation of the same type ('imperfective viewpoint'). Here, we are in an area where tense interacts with aspect (grammaticalized viewpoint) and *aktionsart* (or actionality; the internal temporal structure of situations). Thus, many languages distinguish formally between perfective and imperfective aspect within the past tense.

Instead of making a grammaticalized three-way distinction among present, past, and future tense, as in (1), many languages make only a two-way distinction between past (E < U) and nonpast; this is the case in, for instance, Finnish. Whether there are languages that have the two-way opposition future versus nonfuture is more controversial, and no languages have been cited with a two-way opposition present versus nonpresent (in which case, the nonpresent would have to be discontinuous in its range). In general, the future tense is less stable as a grammatical category than the past tense; it is often expressed periphrastically.

Many languages make additional grammaticalized distinctions within the past or future based on the amount of time separating E and U, that is, the degree of remoteness between them. For instance, in Cocama (Cocama-Cocamilla), a language of Peru, three degrees of remoteness are distinguished in the past, as shown in (3).

(3a) ritama-ca tuts-ui
town-to go-PAST$_1$
'I went to town today'
(3b) ritama-ca tutsu-icuá
town-to go-PAST$_2$
'I went to town yesterday/a few days ago'
(3c) ritama-ca tutsu-tsuri
town-to go-PAST$_3$
'I went to town a long time ago'

Tenses characterized by different degrees of remoteness are rather rare in European languages but widespread among languages of sub-Saharan Africa, Australia, New Guinea, and many parts of the Americas. A two-way distinction is the most widespread, although up to a five-way distinction has been reliably reported for some languages. Some languages have divisions based on the daily cycle, in particular concerning the past, the most common cut-off point being today versus previous days (hodernial vs. prehodernial past); but mostly the division is less specific (immediate vs. remote past or future).

Another relevant parameter concerning the past or future is (in)definiteness. Some languages make a grammaticalized distinction between the definite and indefinite future, the former referring to a future event, the location of which is given by the context, whereas the latter is used when no specific future time is under consideration. And in English, among other languages, the choice between the simple past and the present perfect is partly governed by the same criterion; for example, (4a) differs from (4b) by indicating that the speaker has a specific past occasion or time in mind.

(4a) did you go to Paris?
(4b) have you been to Paris?

Focal versus Nonfocal Tense Meanings

Viewed from a crosslinguistic semantic perspective, tenses can be conceived as prototypes or idealized conceptual categories (sometimes called 'gram types') that tend to be grammaticalized across languages but whose individual realizations (the individual language-specific grams) may differ from one another in detail while sharing the same focal properties. For instance, the present tense normally establishes a relation of overlap between the event time and the utterance time, as in English (1a) and German (5a).

(5a) das Klima änder-t sich
the climate change-PRES.3.SING PRON.REFL
'the climate is changing'

But German (and many other languages) may also use the present tense under conditions in which the future tense could be used, too, as in (5b). That is, the German present tense covers part of the semantic

Figure 1 Interpretation of (2a): *half an hour ago, John was in the garden.*

Figure 2 Interpretation of (2c): *half an hour ago, John left the house.*

space that also falls under the periphrastic future tense and that may demand the future tense in English.

(5b) das Klima änder-t sich bald
the climate change-PRES.3.SING PRON.REFL soon
'the climate will soon change/be changing'

However, this use does not represent the focal meaning of the present tense in German or any other language. In a case such as (5b), it depends crucially on the cooccurrence of a future time adverbial (or other contextual information) indicating the location of E (definite future). In (5c), on the other hand, the futurelike interpretation of the present tense hinges on the nature of the described situation.

(5c) mein best-er Kollege verläss-t die Uni
my best-NOM.MASC colleague leave-PRES.3.SING the university
'my best colleague is going to leave/is leaving the university'

The act of leaving, or the end point of that act, lies ahead of the utterance time; but the intention, and probably some preparatory activities, leading up to the final act are taken to hold at the time of utterance. Thus, this kind of (immediate) future is situated between the focal areas of present and future tenses, that is, situations that evidently hold at the time of utterance, on the one hand, and future situations that are predicted but not yet 'initiated' (by intention, decision, or schedule) at the time of utterance, on the other hand; see (5d).

(5d) das Klima wird sich änder-n
the climate will PRON.REFL change-INF
'the climate will change'

A comparison of (5a), (5b), and (5d) shows that, in German as in English, in the absence of other indications of future reference, the future tense is demanded in order to ensure the intended interpretation.

It follows from this discussion that competition between tenses – across languages and within a single language – is a natural phenomenon, to be expected in domains that, viewed from a crosslinguistic perspective, are not focal to the competing tenses. The sentence pair (6a) and (6b) illustrates the same point with respect to another pair of tenses.

(6a) wir wohn-en seit 1990 in Berlin
we live-PRES.3.PL since 1990 in Berlin
'we have lived/have been living in Berlin since 1990'

(6b) vi ha-r boet
we have-PRES lived
i Berlin siden 1990
in Berlin since 1990
'we have lived/been living in Berlin since 1990'

The German sentence (6a) and the Danish sentence (6b) both state that we live in Berlin at the utterance time and that the situation of our living in Berlin goes back into the past until 1990. (In fact, (6b) has a second, existential or indefinite interpretation to the effect that we lived in Berlin for a certain period located between 1990 and the utterance time but not including the latter.) A reference to a situation holding at the utterance time calls for the present tense, whereas a reference to a time span extending backward from and including the utterance (or orientation) time, called the 'extended now,' falls under the focal domain of an anterior or perfect tense, for example, the present perfect in English. In this domain, in which both tenses are motivated, German prefers the simple present, as illustrated in (6a), although the (present) perfect does occur, too; in Danish, however, (as in English) only the perfect is allowed, as in (6b).

Tense in Context: Pragmatics of Tense

Tense is only one of several ways in which languages can convey information concerning location in time; and the lexical resources in any language for expressing location in time are much richer than the grammatical devices. Thus, sentence–initial adverbials such as *in June 2004, yesterday,* and *in 2 months* provide more precise temporal frames for the situation time E than can apparently be done by the past or future tense alone.

(7a) in June 2004, Venus passed the sun
(7b) yesterday, the weather was really bad
(7c) in 2 months, my colleague will leave for Australia

In the examples in (7), the time adverbials restrict or specify the abstract past or future time reference established by the tenses; the tense itself may in fact seem quite redundant because, as far as the location of E is concerned, it does not add anything to the information conveyed by the adverbial. But the examples in (8) and (9) demonstrate that, conversely, tense can help restrict the interpretation of time adverbials: Because *on Sunday* does not specify its relation to the utterance time, it is the finite tense in (8a) and (8b) that indicates which Sunday is meant.

(8a) on Sunday, my colleague left for Australia
(8b) on Sunday, my colleague will leave for Australia

And in (9), with *this week* referring to the week surrounding the utterance time, the tenses specify the location of E with respect to U within that week.

(9a) this week, the Beatles gave a concert

(9b) this week, the Beatles are in town
(9b) this week, the Beatles will give a concert

In other words, tense and frame-setting time adverbials cooperate in narrowing down the temporal location of E. Consequently, they should not point in different directions. Example (10), in which a future time adverbial cooccurs with past tense, does not allow a coherent interpretation – at least not without further context.

(10) tomorrow, Peter left for Glasgow

Often, however, adverbials or other lexical means are not needed in order to identify the time under consideration in sentences concerning past or future time; it may be deduced by pragmatic reasoning, drawing on the linguistic and nonlinguistic context of the sentence. For example, a question such as (11a) would normally be interpreted as referring to the same day or evening and not the entire preceding week or the entire lifetime of the hearer. In (11b) and (11c), each of which contains two sentences, the E of the second sentence is understood as overlapping the situation time of the parenthesized sentence; in narrative discourse, we preferably take the relative order of sentences as mirroring the order of the events described, as in (11d).

(11a) have you had dinner?
(11b) (we spent the summer in Italy –) did you visit your sister?
(11c) (we shall spend the summer in Italy –) will you visit your sister?
(11d) he went to the phone and dialed zero; a woman's voice answered

Relative Tenses and the (Present) Perfect

Relative tenses differ from absolute tenses by locating the situation time E not directly with respect to the utterance time U but as preceding or following a secondary time of orientation O that, in its turn, may precede, follow, or overlap with the utterance time. Because the utterance time does play a role, albeit indirectly, 'absolute-relative' might be a more adequate term, as suggested by Comrie (1985). Compared to anterior (or perfect) tenses, which express the relation 'situation time precedes time of orientation' (e.g., *had happened, will have happened*), grammaticalized posterior tenses, which locate the situation time after the time of orientation (*would happen*), are quite rare. Relative tenses are often periphrastic or have developed from periphrastic forms that combine auxiliary verbs marked for absolute tense (e.g., *had, will have, would*) with a (nonfinite) participial or infinitival form of the main verb.

Table 2 Schematic representations of past perfect and future perfect

Sentence number	*Tense*	*Definition*	*Formalism*[a]
(12a)	Past perfect/ anterior	Situation time precedes orientation time, and orientation time precedes utterance time	E < O < U
(12b)	Future perfect/ anterior	Situation time precedes orientation time, and orientation time follows utterance time	E < O > U

[a]<, precedes; > follows.

Anterior (Relative Past) and Posterior (Relative Future) Tenses

The pluperfect or past perfect (*had happened*) and the future perfect (*will have happened*) belong to the category of anterior tenses; these locate the described situation (E) prior to the time of orientation (O), which, in turn, is located before (past perfect) or after (future perfect) the time of utterance. Compare the formulas in Table 2 and the corresponding examples (12a) and (12b) with the formulas in Table 1.

(12a) (Roald Amundsen and his team left their base camp in October 1911) by the end of December they had reached the South Pole
(12b) (if we start now) we shall have finished the task by five o'clock in the afternoon

In (12a), the cooccurring time adverbial *by the end of December* [*1911*] provides the time of orientation for the past perfect; the tense, then, indicates that the orientation time precedes the utterance time and that the event of reaching the South Pole took place before the end of December 1911; see Figure 3. In (12b), too, the (future) time of orientation ('five o'clock in the afternoon') is indicated by a cooccurring adverbial. In (12c), on the other hand, it is the event described in the first (parenthesized) clause that provides the time of orientation for the past perfect of the second clause; in this case, the time adverbial (*in October* [*1911*]) cooccurring with the past perfect serves as a frame-setting adverbial (as with the absolute tenses), specifying the location of the event

Figure 3 Interpretation of (12a): *by the end of December they had reached the South Pole.*

('leaving base camp') itself rather than the orientation time of the anterior tense; see Figure 4.

(12c) (Roald Amundsen and his team reached the South Pole in December 1911) they had left their base camp in October

In addition to past and future anteriors such as the past and the future perfect in English, grammaticalized expressions of posteriority in the past (see Table 3) are found in many languages; the grammaticalization of future posteriority, however, seems rare. In English, the past posterior is encoded by *would* combined with the naked infinitive; it is used predominantly in indirect or reported speech (or thought), expressing future time relative to the (past) time of the reported utterance, as in (13a).

(13a) (they said) they would start at noon

Past posterior and anterior tenses may even combine into tenses that depend on multiple orientation times. Thus, *would have finished* is the anterior corresponding to the past posterior *would finish*, as in (13b).

(13b) (they said that if they started at noon,) they would have finished the task by five o'clock in the afternoon

Here, the event described as 'start (at noon),' which precedes U, serves as the orientation time (O_1) for the past posterior *would* + infinitive; the time denoted by the adverbial *by five o'clock in the afternoon* follows O_1, as demanded by the posterior, and serves as the time of the orientation time (O_2) for the anterior (infinitive) *have finished*. In the end, then, E (the act of finishing the task) is located prior to O_2, somewhere between noon and five o'clock. That is, the location of E is computed in three steps, as illustrated in Figure 5.

Figure 4 Interpretation of (12c): *they had left their base camp in October.*

Table 3 Schematic representations of past posterior and future posterior

Sentence number	*Tense*	*Definition*	*Formalism*[a]
(13a)	Past posterior	Situation time follows orientation time, and orientation time precedes utterance time	E > O < U
(13b)	Future posterior	Situation time follows orientation time, and orientation time follows utterance time	E > O > U

[a]<, precedes; > follows.

The (Present) Perfect

From a formal point of view, the (present) perfect in English (e.g., *has happened*) differs from the past perfect (*had happened*) merely by the present versus past tense auxiliary (*has* vs. *had*). Correspondingly, as far as its semantics is concerned, the perfect can most adequately be understood as a relative (anterior) tense, differing from the past and the future perfect with respect to the relation between O and U. In the default case, its time of orientation may neither precede nor follow the time of utterance; that is, the time of orientation has to overlap – or be identified with – the time of utterance, as in (14a) and (14b). Thus, the (present) perfect can be represented as in Table 4; compare these formulas with the formulas in Table 2.

(14a) my colleague has left for Australia (so I am alone on the job now)

(14b) I have been waiting for two hours (so I'm leaving now)

The fact that the perfect locates the described event prior to the time of utterance, either directly or by way of an intermediate time of orientation, obviously brings it into competition with the simple past tense.

Tenses sharing the focal semantic properties of the English (present) perfect are widespread in the

Figure 5 Interpretation of (13b): *we would have finished the task by nine o'clock in the afternoon.*

Table 4 Schematic Representations of Present Perfect

Sentence number	*Tense*	*Definition*	*Formalism*[a]
(14a), (14b)	(Present) perfect/ anterior	Situation time precedes orientation time, and orientation time overlaps utterance time	E < O o U

[a]o, overlaps; <, precedes.

languages of the world. Typically, they have developed from resultative constructions that express that a state obtains at the time of orientation as a result of a preceding event; as a consequence, they typically differ from the simple or general past by not demanding (or not allowing) a more specific location of the situation time, functioning as indefinite pasts, on the one hand, and indicating the current relevance of the past event, on the other; compare the examples in (14) and (15).

(15a) he has gone
(15b) I have invested a lot of money in oil activities

Thus, in contrast to the sentences in (15), the corresponding past tense sentences in (16) demand a context providing a specific temporal frame in the past:

(16a) he went (away)
(16b) I invested a lot of money in oil activities

However, the prototypicality of the (present) perfect varies a great deal across languages. In German, for instance, the present perfect is freely compatible with time adverbials that indicate the location of the event time; that is, it can be used as a definite past, as in (17).

(17) mein Kollege ist neulich/1999
my colleague be.PRES recently/1999
nach Australien gegangen
to Australia go.PP
'my colleague recently/in 1999 went to Australia'

Deviating from the Default Use

So far, we have concentrated on the default uses of the absolute and (absolute-)relative tenses – the (directly or indirectly) deictic use taking the utterance time as the primary point of departure. As with grammatical categories in general, tenses can also be used in non-default ways. One such case is the historical present, as in (18).

(18) yesterday evening, I'm sitting in my office when all of a sudden the whole damn building starts to shake . . .

The initial time adverbial, among other things, indicates that the speaker is talking about past events, and the interpretation of the present tense is adjusted accordingly; that is, the time of utterance is cancelled as the distinguished time of orientation or shifted to the time of the current situation described in the text. Likewise, if someone telephones me and says (19), I am unlikely to interpret this as a description of his or her desires at some point in the past unless I know she or he has a specific past occasion in mind (definiteness condition); rather, I will assume that she or he is talking about the time of utterance, using the present instead of the past to soften the request:

(19) I just wanted to ask you if you could drive me into town today

In both cases, pragmatics 'wins' over semantics, so to speak: Working from the hypothesis that the speaker intends to convey meaningful and relevant information, the hearer may take apparent deviations involving tense as an instruction to interpret the tense in a nonstandard way. It is the same kind of pragmatic reasoning that accounts for free indirect discourse or reported speech, as illustrated in (20).

(20) (Pete didn't want to go/Pete refused to go) now was his last chance to talk to her; his plane left tomorrow . . .

On the face of it, there is a mismatch between the deictic frame-setting adverbials (*now, tomorrow*) in (20), which serve to locate the described situation around or after the time of utterance, and the past tense (*was, left*), which demands an event time prior to the time of utterance. The conflict is solved by interpreting the adverbials from the perspective of the protagonist (Pete), that is, relative to the now of the person whose speech or thought is reported, and ascribing the past tense to the (reporting) speaker, taking it to indicate that the act of thinking or speech whose content is reported in the relevant clauses (and presumably the situations described in those clauses, too) precedes the act of reporting.

In subordinate indirect speech embedded under a past tense verb of saying, English makes use of past tense verb forms in a similar back-shifted way, corresponding to the present tense in direct speech, as in (21). In other languages (e.g., Russian), tense forms remain unshifted in indirect speech; the time of the reported speech act described in the matrix clause simply replaces the time of the reporting utterance as the time of orientation for the present and past tense (logophoric tense).

(21) Pete said he didn't want to go since this was his last chance to talk to her

In certain subordinate clauses, the English past tense may also be used as a relative past (i.e., as an anterior tense) indicating that the situation described in the subordinate clause precedes the event of the matrix clause, irrespective of the relation between the former and the primary time of utterance. Thus, the past tense may in fact refer to an situation that is located after the time of (the reporting) utterance; this will be the case if (22), for instance, is uttered on June 23.

(22) when Anna returns in a fortnight or so, she will probably claim that she arrived on June 25

These observations show that the use and interpretation of tenses in syntactically embedded positions are governed by specific rules, allowing or forcing the event time of the matrix clause to serve as the primary time of orientation for the embedded tense, instead of the time of utterance (speaker's now).

Summary and Outlook

Generalizing over the formulas in Tables 1–4, we can represent the abstract meaning of tense as shown in (23), where Rel symbolizes the basic ordering relations (<, >, and o) and * indicates that the introduction of a secondary time of orientation may be repeated.

(23a) semantically simple tense: E Rel O_1
(23b) semantically composite tense: E [Rel O_2]* Rel O_1

In the default case, the time of utterance serves as the primary time of orientation ($O_1 = U$); but under certain syntactic or pragmatic conditions, O_1 may be some other contextually given time.

Anterior and posterior tenses differ from the simple past, present, and future tenses by being semantically complex. They demand for their interpretation one or more secondary orientation times, depending on their formal complexity.

Finally, it should be stressed that the category tense is strongly intertwined not only with *aktionsart* and aspect but also with modality and the grammatical category mood. Understood in a broad sense, the category aspect covers distinctions between events and resultant states (cf. *to go* vs. *to be gone*), between situations viewed as wholes from the outside and situations viewed from the inside (cf. *to fall asleep* vs. *to be falling asleep*), and between individual events and iterated events or habitual actions (cf. *I went to the opera* vs. *I used to go to the opera*). In fact, the interaction between tense and aspect is so close that pure tense systems are rare in the world's languages; mostly, we encounter mixed tense-aspect systems.

The interrelation between tense and mood/modality is also intimate. Thus, many languages use past and past posterior tense forms to express irrealis or counterfactuality with respect to nonpast time; and (present) perfect tense often acquires evidential (inferential or reportative) meanings. In particular, it can be (and has been) disputed whether future tense is really a tense, given that the epistemic status of the future, as viewed from the speaker's perspective, is necessarily very different from that of the present and the past tense: The speaker cannot know what will be in the same sense that she or he can know what is or has been. This explains the facts that future tense often has a modal origin (e.g., English *will/shall* + infinitive) and that future tense, including the future perfect, irrespective of its origin, tends to develop an epistemic or inferential use referring to present or past time, as illustrated by the German sentence (24a) and the English sentence (24b).

(24a) du wirst müde sein
you AUX.PRES.-2.SING tired be.INF
'you will be/are probably tired'
(24b) we will have finished the task by now

Tense and Time: Philosophical Aspects

L N Oaklander, University of Michigan–Flint, Flint, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

As we ordinarily think and talk about time, it is a truism that time passes. Dates, like the events that occur at those dates, are once in the future, then become present, and then recede into the more and more distant past with the passage of time. To think of time as passing, and events as changing with respect to the characteristics of pastness, presentness, and futurity, is to conceive of the transient aspect of time or temporal becoming. The most fundamental debate in the philosophy of time concerns the status of temporal becoming. Do events **really** pass from the future to the present and into the past, as tensed- or A-theorists (derived from McTaggart's 1908, 1927 A-series of past, present, and future moments or events) such as C. D. Broad (1923, 1938), Richard Gale (1968), A. N. Prior (1967), George Schlesinger (1980), Quentin Smith (1993), Storrs McCall (1994), Michael Tooley (1997), William Lane Craig (2000a, 2000b), and others have maintained? Or is the passage of time a myth and an illusion, as B-theorists (derived from McTaggart's B-series of events ordered by the relations earlier, later, and simultaneous) such as Bertrand Russell (1915), J. J. C. Smart (1980), Robin Le Poidevin (1991), D. H. Mellor (1998), L. Nathan Oaklander (2004b) and others have maintained? That is one issue. Another closely connected issue concerns the proper analysis of tense in ordinary language and thought. We express the passage of time (or the myth of passage) by means of tensed discourse and tensed beliefs. For example, we ordinarily say, at different times, that an event will occur, is occurring, and did occur, and it is commonplace to believe that, for example, today is Monday, tomorrow will be Tuesday, and yesterday was Sunday. Two questions of analysis concerning these ordinary tensed sentences and beliefs immediately arise: (1) What is the meaning of tensed discourse? and (2) what are the truth conditions or truthmakers of tensed sentences? A third issue, intimately related to the other two, concerns the reference of temporal indexicals (such as now,' 'yesterday,' and 'tomorrow'). Do temporal indexicals refer directly to some items (such as times or sentence tokens); or do they refer indirectly to items via a mediating sense (such as the property of **presentness**); or do they, perhaps, perform both functions, or neither?

Although these issues are fundamentally metaphysical in nature, the dispute between the A- and B-theorists has, until the 1980s, centered on temporal language. Defenders of the B-view have often argued that since tensed discourse could be eliminated or translated without loss of meaning into tenseless discourse, an adequate account of the nature of time need not countenance any special kind of tensed fact or tensed properties. In other words, the old B-theory of time assumed that a logical analysis of ordinary language that eliminates tensed discourse supported an ontological analysis of time that rejects transient temporal properties of **pastness**, **presentness**, and **futurity**, or any other form of passage. The A-theorist shared that assumption, but argued that since no tenseless translations were successful, temporal becoming in some form or another is necessary in any adequate account of time. A-theorists claim, in other words, that because tensed discourse is ineliminable, the B-theorist is mistaken and tensed properties and facts must exist.

For a variety of reasons, some having to do with arguments in the philosophy of time and some having to do with arguments in the philosophy of language, recent defenders of the B-theory have come to embrace the thesis that tensed sentences cannot be translated by tenseless ones without loss of meaning. The reason for this is clear. It is part of the meaning of sentences reflecting temporal becoming that they change their truth value with the passage of time. For example, a token (or instance) of the sentence type 'I will be celebrating my 60th birthday in the future' is true today, on January 7, 2005, but in six months another token of that sentence will be false. On the other hand, it is part of the meaning of tenseless sentences expressing temporal relations between events that different tokens of the same tenseless sentence have the same truth value whenever they are expressed. Thus, for example, the linguistic meaning of the sentence (S) 'My 60th birthday is future' cannot be captured by (V) 'My 60th birthday is later than January 7, 2005' even if (S) is uttered on January 7, 2005, since (V) is always true, whereas on July 7, 2005 (S) is not.

Nevertheless, recent B-theorists have denied that the ineliminability of tensed language and thought entails the reality of temporal properties or temporal becoming. According to the new B-theory of time, our need to think and talk in tensed terms is perfectly consistent with its being the case that time itself is tenseless. Tensed discourse is indeed necessary for timely action, but tensed facts are not, since the truth conditions of tensed sentences can be expressed in a tenseless metalanguage that describes unchanging temporal relations between and among events.

There are two popular versions of the new B-theory of time, the token-reflexive account (Mellor, 1981) and the date-analysis account (Smart, 1980). On the token-reflexive account the temporal relation between the date at which one says, thinks, or writes down a tensed sentence and the event or thing that it is about provides an objective basis for the truth-value of any tensed sentence. A present-tense sentence token is true if, and only if, it occurs (exists tenselessly) at (roughly) the same time as the event it is about; a past-tense token is true if, and only if, it occurs at a time later than the event it refers to, and so on. Thus, on the token-reflexive account the truth conditions of tensed sentence and judgment tokens are tenseless facts – that is, facts that involve only temporal relations between and among nontensed events.

The date-analysis version of the new B-theory also denies the thesis of linguistic reducibility and claims instead that corresponding to every tensed sentence-token is a tenseless sentence that gives its truth conditions. For example, J. J. C. Smart (1980) claims that

> the notion of becoming present seems a pretty empty notion, and this is even more obvious when we recognize the indexical nature of words like 'present', 'past' and 'future'. When a person P utters at a time t the sentence 'Event E is present' his assertion is true if, and only if, E is at t. More trivially, when P says at t 'time t is now' his assertion is true if, and only if, t is at t so that if P says at t 't is now' his assertion is thereby true" (1980: 11).

The heart of the date-analysis thesis is that temporal indexicals like 'now,' 'this time,' and 'the present,' as used on a given occasion, are referring terms that denote a time. Thus, if a temporal indexical sentence such as 'Event E is now occurring' is uttered at t_1, then it reports an event that is identical with the event reported at any time by the use of the nonindexical sentence 'Event E is occurring at t_1.' On this view, indexicals and proper names such as dates are rigid designators (Kripke, 1980). Thus, a tensed sentence like 'It is now 1980,' uttered in 1980, reports the same fact as the necessary truth reported by 'It is 1980 in 1980' or '1980 is at 1980.' It does not follow, nor is it part of the date-analysis thesis to maintain, that 'It is now 1980' and '1980 is at 1980' express the same proposition or have the same meaning (Beer, 1988). Nevertheless, to know that the truth condition of a tensed sentence token is a function of the date of its occurrence, and what it is about, is to know the meaning of a tensed sentence (Mellor, 1998).

Both versions of the new B-theory have been the subject of considerable debate. Proponents of the A-theory have argued that the B-theory cannot give an adequate account of the truth conditions of A-sentences, whereas B-theorists have denied this (see Oaklander and Smith, 1994, Part I; Le Poidevin, 1998; Smith, 1999; Craig, 2000b; Mozersky, 2000; and Dyke, 2002, 2003a). More recently, Oaklander (2004a) has argued that tensed sentence-tokens and the mind-independent contents they express, while pragmatically useful and perhaps indispensable, are strictly and metaphysically false and couldn't possibly be true since McTaggart's paradox (to be considered shortly) has demonstrated that the A-theory of time is contradictory.

In summary, the issue that now rages between the various camps in the A/B-theory debate concerns the truth conditions of statements that reflect temporal becoming and temporal relations. In this context, truth conditions are truthmakers: the basis in reality for those true sentences that record facts about the transitory and temporal relational aspects of time. Thus, the A/B debate centers on the questions: What, if anything, do the tenses and our use of temporal concepts reflect about the metaphysical nature of time? And, What is the ultimate metaphysical foundation of our experience of succession and temporal relations? To deal with these questions it is necessary to consider McTaggart's paradox.

McTaggart maintained that becoming is an essential feature of temporal reality, since without real passage there is no change, and without change there is no (B-) time. If events simply stand in the unchanging relations of earlier/later than, nothing would first have a property and then lose it. Thus, in order for there to be change, it must be the case that events have the properties of pastness, presentness, and futurity and change with respect to those determinations. McTaggart argued, however, that such change was impossible. For if every event **is** past, present, and future, then since A-characteristics are incompatible, we arrive at a contradiction. Of course, the seemingly obvious way out of the 'paradox' is to appeal to tense: it is not the case that every event **is** (simultaneously or tenselessly) past, present, and future, but rather every event either is past, was future and present; or is present, will be past, and was future; or is future and will be past and present. This way of avoiding the paradox is well taken, but it certainly is not the last word, since we need to understand how the tenses 'is now,' 'was,' and 'will be' are to be interpreted if we are to understand how such an account is to render temporal becoming possible.

A currently fashionable A-view of the tenses is called 'presentism.' According to this view, only the present exists; the past and future are species of unreality, that is, the past and future tenses are operators (with no ontological significance) on present tense sentences (Prior, 1967; Hinchliff, 1996). Given that

only the present exists, there is no longer any problem of how one and the same event (or moment) can have incompatible A-determinations, since there is only one A-characteristic, namely presentness.

Nevertheless, presentism is not without its difficulties. To see why, suppose we start with

FPe & *Ne* & *Pfe*

This is read as '*e* will be past' and '*e* is present' and '*e* was future.' Perhaps there is no contradiction in such a representation of becoming, but we are still left with the question: What are the truthmakers for the first and last conjuncts? More specifically, what is the ontological difference between *FPe* and *PFe,* given that neither 'F' nor 'P' is a predicate that ascribes properties to *e*? Without such an account, the appeal to grammatically consistent tensed statements is a vacuous response to McTaggart's paradox.

The B-theory, in rejecting temporal passage as an objective feature of reality over and above the tenseless existence of events spread along the four-dimensional manifold, avoids McTaggart's conundrum, but it has questions of its own to answer. If events don't really pass, then why do we talk as if they do? And if nothing is really present, then what account can be given on the presence of experience, and our experience of the present? (For a discussion of proposed solutions to these questions see Oaklander and Smith, 1994, Part III; Dyke and Maclaurin, 2003; and Oaklander, 2004b, Part III).

Tense, Mood, Aspect: Overview

Ö Dahl, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Most languages have more or less elaborate ways of differentiating grammatically the form of sentences depending on parameters such as the character of the event, state, or process that is related in the sentence, how it relates temporally to the speech act and to other temporal entities, the epistemological and pragmatic character of the speech act and the speaker's degree of commitment. These grammatical devices – typically manifested as inflections on verbs or as periphrastic constructions involving auxiliaries or particles – are traditionally treated in grammars in terms of the grammatical categories of tense, mood, and aspect (often abbreviated as TMA or TAM).

While time is fairly uncontroversially the notional category behind tense (in many languages, the terms for time and tense are identical), mood and aspect are more difficult to pinpoint semantically – in particular, their relationship to broader notions such as modality and aktionsart or aspectuality is controversial. For discussions, *see* **Mood and Modality in Grammar** and **Aspect and Aktionsart**, respectively. Although evidentiality is traditionally subsumed under mood, it is nowadays sometimes seen as a category of its own, with information source as its primary meaning (*see* **Evidentiality in Grammar**).

In actual grammars, the categories tend to shade into each other: grammatical forms tend to combine elements from more than one of them, or to fall in between the definitions. There is also a continuum between grammar and lexicon in particular in the areas of mood and aspect. An alternative approach is thus to downplay the role of the supercategories tense, mood, and aspect and focus more on individual types of markings (gram types) such as futures, perfects, perfectives etc., since this level seems most promising when looking for cross-linguistic generalizations (Dahl and Bybee, 1989). In this connection, the study of the ways in which markings of tense, mood, and aspect develop historically – how they grammaticalize – becomes of particular importance.

A number of articles in this Encyclopedia are devoted to different subtopics within the area of tense, mood, and aspect. The traditional categories and their relationship to the corresponding are discussed in the articles **Tense, Mood and Modality in Grammar**, and **Aspect and Aktionsart**. Future tenses, which are often said to be as much modal as temporal, are treated separately in **Future Tense and Future Time Reference**, while perfects, which have a similar intermediary status between tense and aspect, are discussed together with the related categories of experientials and resultatives in **Perfects, Resultatives, and Experientials**. While the article **Aspect and Aktionsart** discusses the general notion of grammatical aspect and its relationship to lexical semantics and the general taxonomy of temporal entities, the major aspectual gram types are dealt with in **Perfectives, Imperfectives, and Progressives**. For logical and philosophical approaches, *see* **Event-Based Semantics**, **Modal Logic**, **Temporal Logic**, and **Tense and Time: Philosophical Aspects**.

The literature on tense, mood, and aspect is immense. Here, only a few general works are listed; for more comprehensive bibliographies, see the articles listed in the previous paragraph.

Terminology and Terminological Databases

K-D Schmitz, Fachhochschule Köln, Köln, Germany

© 2006 Elsevier Ltd. All rights reserved.

What Is Terminology?

> Terminologists, maybe even more so than other subject-field specialists, have problems agreeing on the terminology that they use within their own discipline. (Wright and Budin, 1997: 325)

This statement of Wright and Budin was both well put and accurate, for terminology scientists and terminology workers don't use the term *terminology* with an unequivocal definition. In its first meaning, terminology is the "set of designations belonging to one special language" (ISO 1087–1, 2000). This definition is used when we refer, e.g., to the terminology of mechanical engineering or the terminology of medicine. Some experts also differentiate between the set of terms itself and the publication of these terms in (terminological) dictionaries. A second interpretation of terminology refers to the scientific discipline that studies "the structure, formation, development, usage and management of terminologies in various subject fields" (ISO 1087–1, 2000).

A clear distinction between these two meanings of terminology is necessary, not just for the purpose of this article. Following the definitions in the German terminology standard DIN 2342 (2003), of Wright and Budin (1997: 325) and other authors, 'terminology' is the (structured) set of concepts and their representations in a specific subject field. The second meaning of terminology is called 'terminology science' (or terminology studies, but not terminology) and is defined as the scientific discipline dealing with concepts and their representations in special languages.

Why is Terminology so Important Today?

The present age is characterized by an increase in knowledge in almost all technological, economic, political, and cultural fields. Modern communication and publication methods and media allow the swift and broadscale transfer of this knowledge. But the spread of knowledge is not limited to a closed group of specialists or to one language community. Translators and interpreters play an important role in this multilingual communication process across language boundaries.

Since a high percentage of specialized knowledge is documented and published by means of language, correct terminology is a prerequisite for efficient knowledge transfer. All people who are involved in any way with special language texts must deal with the terminology of the domain in question, whether they function as experts who must read and understand texts, as technical writers who produce texts, or as technical translators who transfer their content into another language.

Historical Development of Terminology Science

The need to define and compile terminologies was recognized at the time when special and professional languages were developing. Individual scientists, researchers, and engineers from the 15th century onward have been concerned with the definition and ordering of the knowledge of their respective domain, and with the preparation of terminologies, such as Leonardo da Vinci in engineering, Gottfried Wilhelm Leibniz in mathematics, Albrecht Dürer in geometry, Antoine Laurent Lavoisier in chemistry, Carl Linnaeus in biology, and others. Another pioneer in developing multilingual terminological dictionaries was Alfred Schlomann, who published systematically arranged vocabularies for 17 different subject fields between 1907 and 1932. Each of these comprehensive technical dictionaries was developed by a team of subject field specialists, applying 'terminological' guidelines defined by Schlomann.

Also at the beginning of the 20th century, national and international standards organizations were founded to support technical cooperation by defining and specifying properties of parts and tools. Soon after the establishment of technical committees for standardization, terminological subcommittees were founded to define and standardize the technical vocabulary of the different domains. The dissertation of the young Austrian engineer Eugen Wüster, published in 1931 under the title 'Internationale Sprachnormung in der Technik' ('International standardization of language in technology'), provided the impetus for the foundation of ISA's Technical Committee TC 37 'Terminology and the preparation of terminological principles', which was re-founded after World War II as ISO/TC 37. Wüster was not only the founder of the General Theory of Terminology (see Wüster, 1991 and Picht and Schmitz, 2001), but he was also engaged very much in the creation of the first international terminology standards, improving and testing the standards by elaborating and compiling his systematic terminological dictionary *The machine tool*.

Wüster is often called the founder of the Vienna School of Terminology. Felber (1984) also described the Prague School of Terminology (developed from the

Prague School of functional linguistics) and the Soviet School of Terminology (D.S. Lotte and E.K. Drezen). Basic research in terminology principles and theory took place in Canada, Germany, the United Kingdom and in the Nordic countries in the second half of the 20th century. Today we find terminological activities also in other parts of the world, especially in Spain, France, North and South America, and in China.

The Basic Theoretical Background for Terminology Management

This section will present the basic principles and fundamental concepts treated in terminology science, focusing on those aspects that are essential for performing practical terminology management activities and establishing terminological databases. Of course, this article cannot cover all theoretical and practical aspects. For more detailed treatments of the entire field of terminology studies and terminology management activities, see in particular Arntz *et al.*, 2002; Dubuc, 1992; Felber and Budin, 1989; Sager, 1990; Wright and Budin, 1997, 2001; and Wüster, 1991.

Over time, people who have to deal with terminology have developed methods and procedures for managing terminology. These basic principles governing terminology activities and management have developed into a scientific discipline, which has itself been called 'terminology science' or 'terminology studies'. Both the definition of terminology and the general principles of terminology science deal with concepts and terms. Originally, terminology theorists and researchers adapted the so-called "semiotic triangle" introduced by Ogden and Richards (1923) to explain the relationship between concepts and terms (Figure 1).

The triangle has undergone a long history of modifications and interpretations, and has also been attacked from several quarters as an oversimplification or misrepresentation of the complex relationships that exist between concepts and terms, concepts and concepts, and terms and terms. Despite the criticisms that have been leveled against the triangle, its simplicity makes it an excellent tool for illustrating concept-term relationships to people who are just beginning to identify terms in texts, and to create terminological data entries to document them. Consequently, we will use the triangle to discuss these three elements, bearing in mind that it is just a useful tool and does not necessarily address complex linguistic, cognitive, or philosophical issues.

Object

An object as represented in the triangle in Figure 1 is an entity existing in the world in which we live.

Figure 1 The terminology triangle.

Objects don't have to be concrete objects, e.g., things you can touch, smell, or see. They can also include abstract objects that are not part of the perceivable world, but that are nonetheless *real* components of human thought.

(1) Example of a concrete object: a computer keyboard.

(2) Example of an abstract object: hyphenation.

It is useful to cast a wide definition for the concept of an *object* and to include more complex states of affairs and even processes within the notion of an object. In this sense, objects can even have a sort of propositional nature and be represented by collocations and phrases, such as: 'hyphenation of the current text' or 'format a new diskette'.

Wüster (1991) clarified the notion of the *object* by talking about *individual objects*. He explained that it is not the computer keyboard as such that exists in the world, but rather that there exist numerous individual computer keyboards. The overall class represented by *computer keyboard* comprises a conceptual 'type', for which individual instances of keyboards are 'tokens'.

Concept

Concepts are "cognitive representatives" (Felber and Budin, 1989) for objects, stand-ins, as it were, that arise out of the fact that humans recognize the common characteristics that exist in a majority of individual objects of the same type, and then store these characteristics (e.g., remember them) and use them to impose order on the world of objects, in order to achieve mutual understanding when they communicate with other people. ISO 1087–1 (2000) defined a concept as a "units of knowledge created by a unique combination of characteristics".

Characteristics, as they are understood in this definition, are those properties of the objects in the given class of objects that are used to form and delimit the concept. Modern cognitive science and neuroscience are not in agreement on precisely how concepts are generated or stored in the brain, nor is it totally clear how they come to be associated with specific terms or other conceptual representations. However,

even the strictest empirical research supports the thesis that cognitive units (concepts) are formed in our minds, and we associate these concepts with verbal or nonverbal representations (terms, symbols, etc.).

Concepts are not necessarily bound to specific languages, but the cultural and social background of the human beings who generate the concepts and the environments in which they are used affect the way they manifest themselves in any given situation. Variations in conceptual orientation can reflect cultural and social differences; these are derived from regional differences within a language community, or differences between communities where different languages are spoken, or even different ethnic and class differences between individuals who may only speak variant dialects of the same language, and who live in close contact with one another.

We should also note that one can distinguish between individual concepts and general concepts. An individual concept refers to an individual object, such as the *Starship Enterprise* or the *Cologne Cathedral*, while general concepts comprise the characteristics of a class of objects (*spaceship*, *cathedral*).

Relationships between Concepts and Concept Systems

Concepts can be related to one another based primarily on the characteristics with which they are associated. These conceptual relations can be of a hierarchical or nonhierarchical nature. Hierarchical concept relations can be further divided into generic relations and part-whole relations. Some writers in English speak of hyperonymic or meronymic concept systems.

Generic relations, which are also called logical or abstract relations, are characterized by the fact that a relation can be defined between a broader (superordinate) concept and a narrower (subordinate) concept, such that the subordinate concept contains all the characteristics covered by the superordinate concept, with the addition of at least one additional characteristic. The term designating the superordinate concept is often called a 'hyperonym', and the term designating the subordinate concept is called a 'hyponym'. Concepts that occur at the same level are called 'coordinate concepts', and their terms are called 'co-hyponyms'.

Let us take an example from the evolution of computer hardware.

(3) Example: *printer and laser printer.* A *printer* can be any one of several types of devices that creates an image on paper (or perhaps some other medium, like a T-shirt) representing text or graphics created in a computer program; a *laser printer* is a device that can be defined in precisely this way, with the addition of the characteristic that it uses laser technology to create the image.

Meronymic relations (part-whole, partitive relations) are characterized by the fact that the broader concept (superordinate concept) in this case can be conceptually broken down into its individual components.

(4) Example: A *printer* consists of the *print head, the paper tray, the paper feed, the control panel, the housing, etc.*

Nonhierarchical conceptual relations are defined less frequently than hierarchical ones. These can include, for instance, sequential relations that represent chronological sequences or cause-and-effect relations.

Going beyond comparing just two concepts and looking at many of the concepts or even all of the concepts in a subject field, a conceptual field is created. For these terms to form a concept system, it is necessary to identify a certain order among the concepts. In a closed concept system, i.e. one where all the concepts intended to document a given subject field have been collected, the concepts can be arranged in order according to their concept relation, then each concept is assigned a position number within the system. These systems order concepts according to superordinate and subordinate positions within generic or partitive systems (*x is a y*, or *x has a y*), and they even assign rules for concept behavior at certain nodes in the system. In dynamic systems, meaningful position numbers become problematic because new items are constantly being added at different intersection nodes within the system. In such cases, new views of concept structures can be generated as needed 'at run time,' based on so-called 'parent-child' relationships.

If the intention is to represent a concept system and the concept relations contained in it, it is common to use either a graphical representation or a numerical code. In Europe, it has been common to use tree diagrams to represent generic systems and bracket diagrams for part-whole relations. This distinction has not necessarily been followed in North America, where tree diagrams are commonly used to represent both types of hierarchical relations. When numerical codes are assigned for closed concept systems, the different hierarchical levels (sometimes referred to as levels of abstraction) are assigned different numerical levels. This practice produces numbers where decimal points represent the levels of abstraction. Sometimes dashes are used in part-whole systems to represent levels of meronymic relations. **Figure 2** is an example of a generic system using tree diagrams and notation. **Figure 3** is an example of a part-whole system with a bracket diagram. Sometimes it is useful to create hybrid diagrams showing both generic and part-whole relationships in a graphical or notational system (**Figure 4**).

Figure 2 Tree diagram for a generic concept system.

Figure 3 Bracket diagram for part-whole concept system.

Today in many companies and government agencies, information specialists and knowledge engineers are creating what are often called 'ontologies', or 'taxonomies', showing all the major terms and data objects that are managed in the enterprise's databases and documents. These resources look very much like the concept systems mentioned above because they are usually arranged according to generic or part whole principles. They are generally 'open systems' that are constantly under development and consequently don't have position numbers. One special feature of many ontologies is that the individual nodes in the conceptual structure can be associated with rules. For instance, in a concept system for *vehicles*, there might be an axiom (a rule) that states: *All cars with a crankcase year of 1965 or later are subject to emission control regulations in the state of California*. A computer program or intelligent agent on the World Wide Web could use this kind of axiom to find information and even 'make decisions' based on the ontology and the rules embedded in it.

Term

The third corner of the terminology version of the semiotic triangle is represented by the 'term'. ISO 1087-1 defined the term as a "verbal designation of a general concept in a specific subject field". The term serves as the representation of the concept. We can write it down, think it, say it out loud, use it for communication.

Figure 4 Hybrid concept system for *mouse*.

We use the word 'designation' as a superordinate concept when we talk about terms because there are also other ways to represent terms, e.g., ones that aren't necessarily made up of words, such as symbols, formulas, pictograms, etc.

Example:	H_2SO_4	Sulfuric acid
	™ ®	Trademark, registered trademark
	☎	Telephone
	☠	Poisonous, dangerous
	∞	Infinity

Some terms consist of more than one word. These terms are called multiword terms or compounds. In Germanic languages such as in English and German, multiword terms usually consist of several nouns or adjective noun combinations. The way words combine to form terms varies from language to language.

Example:	
Single-word terms:	printer (Eng); Laserdrucker (Ger)
Multiword terms:	laser printer (Eng); Centronics-Schnittstelle (Ger)
	printer with single-sheet feed (Eng)
	Drucker mit Einzelblatteinzug (Ger)
	serial port (Eng); serielle Schnittstelle (Ger)

Terms always designate class concepts, e.g., *skyscraper* designates all objects that can be defined as buildings that are more than 20 stories tall. Verbal representations of individual concepts (a specific object) are called *names*, e.g., *the Empire State Building* is one specific skyscraper. There is no other building with this name.

There are any number of rules and precedents for forming terms, which we will not outline here (see Arntz *et al.*, 2002; Felber and Budin, 1989; Sager, 1990; Wüster, 1991). As noted above, typical multiword formation patterns differ from language to language (*Typeraddrucker*, *daisy wheel printer*, *imprimante à marguerite*); consequently, the distinction of single and multiword terms is often a fluid one in multilingual terminology management.

Figure 5 Synonymy.

Relationships between Terms and Concepts

We have seen that the term is the verbal representation of the concept. In special or technical language, it is highly desirable that this relationship be unambiguous, even without contextual reference, which means that one term should be assigned to one concept, creating a condition called *univocality*. When this condition prevails, the meaning of terms is completely clear, even if the term appears without any explanatory context. Of course, this ideal situation is difficult to achieve or enforce. Two problems involving term-concept assignment recur frequently, even in technical and scientific texts:

'Synonymy' exists if two or more terms in a given language represent the same concept. Thus a synonym is a term used to designate the same concept as another term (Figure 5).

(5) Example: enter key, input key, return key, carriage return.

Even though synonymy can compromise communication between experts, it occurs quite frequently in practice. This can happen especially in subject fields where many objects and concepts are still undergoing development. In these kinds of dynamic fields, competing terms are used in parallel until unambiguous terms are gradually established, either through a natural selection process or by conscious standardization. Even when people are aware of these problems, variants can remain in use for long periods of time, based on such factors as natural regional variation or, quite intentionally, company or product-specific efforts to use terminological differences as one means of positioning a product in the market.

In some cases, two or more terms are similar in many ways but don't quite totally cover the same concept. Such terms are call quasi-synonyms and are mutually interchangeable only in certain contexts.

'Homonymy' involves the opposite situation from synonymy: here a term or several terms that have the same external form refer to several concepts. ISO 1087–1 (2000) defined homonymy as a relation between designations and concepts in a given language,

Figure 6 Homonymy and polysemy.

in which one designation represents two or more unrelated concepts (Figure 6).

(6) Examples: mouse (animal) vs. mouse (input device for computers)
stud (horse) vs. stud (fastener) vs. stud (architectural framing member)

In English linguistics and grammar, what we are calling 'homonymy' is frequently viewed either from the standpoint of 'polysemy' (words having multiple meanings) or 'homonymy' (concepts having 'homogenized' names). The same word used metaphorically to designate two different things is a polyseme (e.g., mouse (animal) and mouse (of a computer), or stud (fastener) and stud (framing member), which come from the same original linguistic root. Stud (horse) and the two examples of stud as fastener or framing member are, according to this view, 'true homonyms', because the two usages come from different etymological roots. The top section of Figure 6 illustrates the condition of 'polysemy,' i.e., one term represents several concepts, whereas the second half of the illustration reflects true homonymy, where the same word form just happens to represent different concepts (which is what happens with *stud* the horse and *stud* the fastener). Although the distinction between polysemy and homonymy is considered important in linguistics, in terminology management it is not viewed as highly important, because the two phenomena result in the same pragmatic word behavior: the same word form represents more than one concept. In termbases, we often call these duplicate terms 'doublettes', because the same word may occur as an index two or more times in a concept-oriented termbase, each time with a different meaning.

Homonyms pose huge problems for technical communication. As a consequence, experts are constantly striving to avoid homonyms in technical subject fields. Nevertheless, when new concepts evolve, people like to form new terms for them by combining familiar existing terms or by adopting established terms from general language (e.g., *mouse* for a computer input device), from other related subject fields (e.g., the use of terminology taken from steelmaking and glass-making, applied to plastics), and from other (foreign) languages (e.g., the widespread use of English terminology in other languages for various computer applications and in the World Wide Web). Consequently, homonymy frequently occurs at the interface between specialist domains.

The third phenomenon involving the relationship between concepts and terms that plays a role in multilingual terminology management comprises the transition from one language to another. 'Equivalence' is the relation between designations (e.g., two different terms) in different languages, representing the same conceptual characteristics, and thus the same concepts. Of course, as we have already noted, concepts are influenced by social and cultural conditions, and it is not always possible to establish full equivalence. The problem of incomplete equivalence occurs frequently in general language and in certain specialist domains, such as the language of the law when different language communities possess different legal systems. This is even apparent, for instance, when we compare the legal language used in the United States and in Great Britain: sometimes the same terms are used to mean different things, but in other cases, different terms may be used to designate essentially the same concepts. Old technologies like steelmaking and glass-making tend sometimes to designate dissimilar concepts in different languages, because practice and terminology evolved independently in different language communities; but in newer fields like computer science, AIDS research, and genetic engineering term-concept pairs tend to be much more symmetrical between languages, because scientific and technical development in today's world moves ahead in parallel in most major languages. There is a great deal of borrowing and loan translation, which makes it much easier to establish true equivalence between languages.

Essentially, equivalence constitutes the same phenomenon on an interlingual level (e.g., between two or more languages) that we see intralingually (within the same language) when we talk about synonymy.

Equivalence problems can also occur if we draw up concept systems in two or more languages and then try to just transfer concepts from one language to the other or to compare them without taking potential conceptual or systematic differences into account. Sometimes, hierarchical relations manifest themselves differently in different languages or some concepts are missing in some languages (so-called 'terminological lacunae'). For instance, in the area of toolmaking and die-making, German divides tools and processes into *spannende* and *spannlose Fertigung*: chip-forming and non-chip-forming manufacturing. English, in contrast, thinks of these processes as involving *cutting* and *shaping*, and consequently creates hierarchies for tools and processes that may look very different from concept systems created for the same basic subject field in German. Whenever a new object is invented in the real world, lacunae exist until someone decides what to call the new object in a given language. Frequently, terms will be borrowed from other languages to fill these conceptual holes, but just as frequently, the concept covered by the new term in Language B may not be quite the same as the original concept in Language A.

Terminological Databases

The first attempts to use computer technology for managing terminological data started in the early '60s of the last century. There was an urgent need for national and international institutions and for multinational companies with large translating and interpreting services, because very often a great number of translators had to co-operate in large projects under great time pressure, in order to meet deadlines. Due to the restrictions resulting from the hardware and software components available at that time and due to the organizational infrastructure needed for operating mainframe computers, only economically strong organizations and institutions could afford to implement and maintain their own terminological databases. It is therefore not surprising that the first terminological data banks were set up in large language services belonging to governmental organizations and big enterprises, in standards bodies and in language planning institutions, e.g.:

- LEXIS (Federal Office of Languages, Germany)
- TERMIUM (Language service of the Canadian government)
- EURODICAUTOM (Commission of the European Community)
- TEAM (Siemens AG, Germany)
- AFNOR (French Association for Standardisation)
- BTQ (Office de la langue française, Canada)

Most of these large terminological data banks (term banks) have been maintained and used within their respective institutions down to the present day, so that they contain hundreds of thousands of entries. The terminological data in some of the large data

Internet

Figure 7 Eurodicautom terminology database.

banks are also accessible for external users on CD-ROM or via the Internet (Figure 7).

The first generation of term banks with their pragmatic and often institution-specific design was succeeded by a research-oriented development which, on the one hand, helped reveal the conceptual weakness of the individual data banks and, on the other hand, created new concepts, which again led to the development of corresponding software. Examples of this trend are the DANTERM database, developed at the University of Copenhagen, and the Ericsson CAT system, used in the language departments of some German companies and governmental organizations. Both systems are based on a concept-oriented approach to terminology management and run on midsized computers. But with the breakthrough of microelectronics and the burgeoning population of (networked) personal computers even in the environment for terminology work, these systems were replaced by PC-oriented terminology management systems. Today, we find client-server terminology databases that allow web-based cooperative terminology work by terminologists and terminology users across the world. But terminology databases are not just used as stand-alone applications for terminology management, they are also integrated into workbench systems and communicate with word processors, publication systems, translation memories, and machine translation systems. Professional features and additional components for project management, data interchange, and term extraction facilitate comprehensive application in larger language, translation, or terminology services (Figure 8).

Design and Implementation of Terminological Databases

The needs of the different user groups involved in developing and retrieving terminology, as well as the organizational environment in which terminology management takes place, have a strong impact on the

Figure 8 MultiTerm iX web-based sample terminology database.

conceptual design of a terminological database. It is very important to specify the types of data (terminological data categories) that should be managed, and to define the data model (terminological entry structure) that will form the basis of the termbase.

The selection and specification of 'terminological data categories' should be based on ISO 12620 (1999), which lists and describes more than 200 data categories useful for terminology management. According to this standard and other publications dealing with terminology management, terminological data categories can be grouped under various headings, depending on whether they are concept-related or term-related, or contain administrative data.

Concept-related terminological data categories comprise those data elements that refer to the concept underlying a terminological entry or describing the relationship between this concept and other concepts. Typically used concept-related data categories are:

- Definition
- Subject field/domain
- Illustration/symbol/formula
- Classification/notation
- Superordinate concept
- Subordinate concept
- Co-ordinate concept.

Term-related terminological data categories contain those data elements that refer to one particular term representing the concept. The set of term-related data categories must be repeated for each term assigned to the concept, within one language (e.g., for synonyms) or for several languages (e.g., equivalents). Useful term-related data categories are:

Figure 9 Term autonomy realized in MultiTerm '95 Plus.

- Term (including synonyms, abbreviated form, and orthographical variants)
- Term type
- Context/example
- Grammatical information (gender, part of speech, number)
- Geographical restriction
- Linguistic restrictions
- Register
- Project code/company code.

Administrative data categories refer to the entry as a whole, or to individual concept-related or term-related data categories within this entry. Administrative data categories include:

- Identification number (entry number)
- Date (creation/last update)
- Author (creator/checker/editor)
- Source
- Reliability
- Note/annotation/comment.

The selection and specification of terminological data categories is a very important step in the design of a terminological database. Modifications and re-specifications of data categories are very labor- and cost-intensive when the database is already filled with data.

The next step in designing terminological data bases is the definition of the 'terminological entry structure', i.e., a systematically hierarchical arrangement of data categories. ISO 704 (2000), ISO 12200 (1999) and ISO 16642 (2003) provided good guidance for this data modeling process. Two major principles should be mentioned in this context.

Per definition, a terminological entry has to contain all terminological data related to a given concept (ISO 1087–1, 2000). Therefore, the entry structure has to reflect the principle of 'concept orientation', thus allowing for the maintenance not only of all concept-related information, but also of all terms in all languages with all term-related information within a particular terminological entry. Terminological entries designed according to the principle of term

orientation, which we very often find in bilingual glossaries or dictionaries, are not appropriate for meticulous terminology management and will quickly lead to inconsistent terminology collections that are not very useful, especially if multilingual terminology management is required.

The second important principle of terminological entry modeling is 'term autonomy'. Term autonomy guarantees that all terms including synonyms, abbreviated forms and spelling variants can be documented with all necessary term-related data categories. This approach can be realized by designing the data model in a way that allows the user to create an unlimited number of term sections, or term blocks, containing individual terms and all additional data categories describing the term and its use. Figure 9 shows an example of a monolingual terminological entry following the principle of term autonomy.

Terminology, Term Banks and Termbases for Translation

M Rogers, University of Surrey, Guildford, Surrey, UK

© 2006 Elsevier Ltd. All rights reserved.

Preliminaries

The relationship of human beings with their environment, as well as with each other, is mediated through language. Where that environment involves specialist knowledge, a special vocabulary – or 'terminology' – develops to allow specialist concepts to be communicated, both in speech and in writing. Through the ages since classical times, translators have played a key role in the transfer of specialist knowledge from one culture to another (Delisle and Woodsworth, 1995: 101–127), not only in the codification of the terms that, to use a popular metaphor, comprise the building blocks of specialist knowledge, but also in their formation in order to fill lexical gaps in the target language through, for example, circumlocution, neology and borrowing (cf. Rener, 1989: 99).

Much of the stock of specialist knowledge is recorded and developed in texts of various kinds for a range of purposes and different audiences. The translators of specialist texts need support in identifying and using the terminology of the relevant subject in both the source and target languages, as the terms and concepts of specialist knowledge are usually acquired as part of formal training. Such information is contained in what are sometimes collectively called 'terminology resources' (TRs) or 'terminology collections' (Wright and Budin, 1997: 325–326); these may be produced by large commercial publishers, companies, international organizations, or by individuals as professionals (including specialist translators) or hobbyists. Typical examples of TRs include alphabetical or thesaurus-type specialist dictionaries, glossaries, nomenclatures, term banks, and termbases. The need for these resources is of growing importance in the age of the 'knowledge society,' characterized by increasing specialization and globalization. Consequently, dictionaries and other codified terminology resources are unable to keep pace, and translators need to be skilled researchers of diverse resources, including documentation, and even compilers of or contributors to terminology collections themselves.

Terminology of Terminology

The term 'terminology' itself requires comment, as it has several senses. It can refer to a set of principles for compiling terminologies according to concept-based methods (compared to the word-based methods of lexicography; see Wright and Budin, 1997: 328), the application of terminological methods, sometimes also called, by analogy with lexicography, 'terminography' (Rey, 1995: 129), a collection of terms within a particular subject field, and lastly, a published collection of the same (mono-, bi-, or multilingual). In this latter sense, a terminology can be paper or electronic, as also 'glossary,' for example.

Two resource types that are, however, exclusively associated with electronic storage and retrieval are term banks (previously 'terminological data bank' or 'terminology data bank') and termbases (sometimes also equated with 'terminological database' or 'terminology database'). Although distinctions have often been blurred in practice, 'term bank' is usually used to refer to a computerized collection of terminological data (e.g., terms, definitions, usage information, etc.) held and compiled by large organizations. 'Termbase' has achieved more recent currency, leading to what might be called a democratization of terminology resources.

Term Banks

Comparing term banks with termbases, Wright and Budin (2001: 878) suggest that term banks, as a customized type of data bank, "frequently involve more complex features [...] than databases," including "multiple applications, interactive file structures and greater system complexity or size." Term banks may be further distinguished by their broad range of intended users and by being accessible to external users on CD-ROM, online by subscription or with free access, although the latter may lead to problems of overload. One well-known example with free access is the European Commission's EURODICAUTOM, a multilingual bank of 5.5 million entries covering subject fields relevant to European Union (EU) policy. A project to amalgamate EU terminology in an even larger interinstitutional term bank comprising the term banks of a number of EU institutions and bodies was begun in 1999 (IATE: Inter-Agency Terminology Exchange). The issue of quality control when dealing with very large amounts of terminological data has long been recognized as problematic in all large term banks (cf. Picht and Draskau, 1985: 144), although more recent practice is designed to improve overall quality through the structuring of data into defined categories and category sets (e.g., ISO 12620, 1999; Wright, 2001a), as well as through validation procedures within organizations.

Although term banks are usually associated with non-commercial organizations, one pioneering

example in the 1970s of a translation-oriented term bank covering many subject fields was coordinated by the German company Siemens: TEAM (Terminologie-Erfassungs- und Auswertungs-Methode/Terminology Evaluation and Acquisition Method). National standards committees such as AFNOR (Association Française de Normalisation) compile term banks for regulatory purposes within particular subject fields for a wide range of user groups including not only translators and terminologists but also documentalists, engineers, students and trainees. Typically, terminology standards such as AFNOR's and BSI's NORMATERM containing French and English standardized terms are only available against payment.

Term banks are also a tool of bilingual language planning. In the Canadian province of Québec, for example, following the establishment of French as the official language in 1974, an interventionist policy was pursued through the Office de la langue française, particularly with respect to terminology, which was deemed essential to the reintroduction of French in the workplace according to Humbley (1997). The three million terms from 200 subject fields in the French/English/French term bank, Banque de terminologie du Québec (BTQ, now Le Grand dictionnaire terminologique), can be interrogated freely online, as sensibly befits its purpose of dissemination. The mainly bilingual term bank of the Terminology and Standardization Directorate of the Canadian Government Translation Bureau, TERMIUM®, containing over one million entries is, however, only commercially available to external users.

In some cases, term banks are the result of interinstitutional and international cooperation. The Nordic Termbank, for instance, is the result of cooperation between the Nordic countries, which are particularly active in terminology, through Nordterm, an association engaged in terminology work, training, and research. Global cooperation within and between the public and private sectors, as well as nongovernmental agencies, has resulted in a number of multilingual term banks (not always called that). Examples include the multilingual 'terminology databases' (TERMITE and others) of the International Telecommunication Union within the UN system, and FAOTERM of the UN's Food and Agricultural Organization. Many, however, still turn out to be multilingual term lists, sometimes assigned to a subject field, but without the contextualizing information that underpins translation decisions.

Some term bank projects date from the times of mainframe computers in the 1960s; expansion was notable in the 1970s (Picht and Draskau, 1985: 138, 141; cf. Felber, 1984: 378–389 for an early inventory of operational and planned term banks). TERMIUM, for instance, arose from a collaboration between the University of Montreal and the Canadian government in the mid–1970s (Hutcheson, 2001). EURODICAUTOM also was launched around the same time based on legacy data from two institutions. Since the 1970s, term bank organizers have been faced with restructuring exercises necessitated by a number of factors including the migration of data for technological reasons, the problem of managing large amounts of interrelated data, and moves toward greater data interchange (Melby, Schmitz, and Wright, 2001).

Termbases

Termbases are more recent than term banks. To a degree, the claim that they are different is a *posthoc* rationalization, which turns out to have some foundation. Termbases have emerged with the increasing **commercial** availability of software tools – customized databases, commonly known as 'terminology management systems' or 'TMSs' – to store and retrieve terms and their associated data on stand-alone personal computers, as well as in networks. The commercial market is expanding, and translators and their employers are often bewildered by the array of products. Evaluation of such systems according to purpose and technical specification, as well as functionality, is therefore of growing importance (Schmitz, 2001).

TMSs are becoming standard tools for the management of terms and their associated data for translation purposes. Once populated with data, the resulting termbases vary considerably in content, structure and format, depending on software functionality, purpose, resources, and the expertise of the compiler(s). Some may be little more than lists of terms and, if bilingual, their equivalents. Others, as also some term banks, may contain a rich mixture of information, i.e., 'metadata,' supporting the user in the linguistic and conceptual use of the term and often referred to as 'elaboration.' Metadata may include linguistic information (e.g., contextual examples; word class; morphological patterns; collocates), conceptual data (e.g., domain or subdomain; definition or explanation), pragmatic data (e.g., preferred and deprecated use, data on synonyms, variants, abbreviations), and, finally, administrative data used for quality control (e.g., dates and sources of data entry and update). However, without further machine processing of conceptual relations, e.g., through structured definitions, termbases cannot yet become knowledge bases that can, say, relate hyponyms to their co-hyponyms and hyperonym.

It is clear that such complex data need careful modeling and management, as the relations between the different data types are of various kinds. A definition may be related to several terms in a relationship of synonymy or equivalence, whereas a contextual example and linguistic information are related to a specific term in a specific language. Synonyms, abbreviations, and variants (e.g. orthographic or geographical: 'converter' – U.K. English, or 'convertor' – U.S. English) are, of course, terms in their own right and in some database designs, we may speak of 'term autonomy' if each synonym, etc. can in turn become the entry term – or a kind of headword in the language of lexicography – accompanied by its associated linguistic and pragmatic data, allowing translators to make important decisions about which term is appropriate in the context of the translation task.

Freelance translators are, in practice, however, often reluctant to invest in a TMS – now often expensively packaged together with other tools as workbenches – to record their own terminological research, because they fear a steep learning curve. In-house translators also show a reluctance to engage in detailed terminology work, although it is often part of their job to record new terms and their usage. Many freelancers store terms in an *ad hoc* way using record cards, word-processing or spreadsheet packages, or even annotations in the margins of their paper dictionaries. However, such solutions have limits with respect to volume and consistency of data in particular (cf. Wright, 2001b). Many university programs for specialist translation now include training with TMSs in their curriculum, including not only technical skills but also principles of good practice for populating the termbase (cf. Wright, 1997).

Organization of Data

Increasingly, each entry – or database 'record' – in both term banks and termbases is organized around the concept or meaning rather than the term, in accordance with the onomasiological principles of terminology. Consequently, all synonyms, variants, and abbreviations as well as equivalents are grouped together in the same entry (thereby avoiding problematic cross-references), working from the content or meaning/concept to the form or term. Polysemes and homonyms therefore require separate entries. Working from the word to the meaning is the traditional method employed by lexicographers: the semasiological approach (Landau, 2001). The thematic organization of terminologies is often contrasted with the alphabetical ordering of dictionaries, but there is clear historical evidence that many early codified collections were thematically organized (cf. Jackson, 2002: 147–148).

A great deal of hard-won terminology data is underexploited because the data cannot easily be reused, i.e., exported and imported to another system compiled for a different purpose and using different subsets of data categories organized in different structures. For example, translators may compile their own termbases in the process of solving *ad hoc* terminology problems and wish to share with colleagues. Large companies may employ a terminology manager to coordinate and validate the work of in-house translators and large numbers of 'suppliers' (i.e., freelancers). Companies or other organizations using different terminology systems may undergo a company merger. And so on. Consequently, much work has been carried out over the last decade or so on developing so-called interchange formats, which aim to facilitate the reuse or 'leveraging' of data (ISO 12200). The extent to which these standards are applied is unclear; research is needed to clarify their utility and practicability.

Terms and Translation: What Counts as a 'Term'?

Terms, as opposed to words, are difficult to define for a number of reasons, including the level of expertise considered, e.g., the expert's 'automated teller machine' compared to the layperson's 'cash machine', and the degree of specialization, e.g., a dictionary of 'science and technology' or a 'terminology of flexography.' Terms are not simply specialist words, as they exhibit many different morphological and syntactic patterns according to language-typological differences, sometimes leading to demarcation problems with multiword terms. Single-word terms can be roots such as 'disease' or compounds such as the German 'Autoimmunkrankheit.' In English, terms formed by compounding are usually multiword, e.g., 'immune system disorder,' whereas in the Romance languages, terms may take on the form of lengthy phrases such as the French automotive term 'électrovanne de commande de démarrage à froid.'

One of the difficulties that specialist translators and terminologists share is knowing when a particular expression is being used in a general or a specialist sense, as many words do 'double duty' as terms and the equivalent may vary accordingly. The word 'mature,' for example, in the collocation 'mature student,' is a term from the U.K. higher education system that denotes a student who has not come directly from school; it not a euphemistic way of referring to a student's advanced age. Whereas at a system level we may say that there is no equivalent for

such culturally bound terms, in the translation of a **text** a solution must be found. Because the solution is likely to be text-specific, it is questionable whether it belongs in a codified collection of terms.

Other tensions that arise from the different nature of terminologies as system and translations as texts include the treatment of lengthy compounds, which tend to get 'clipped' in the creation of texts. So the 'gas valve outlet flange' becomes the 'flange' at the next mention, and the 'water circulating system' becomes the 'system.' Whereas 'flange' can be entered in a terminology as the hyperonym, it makes little sense to enter 'system.' Translators rely instead on their knowledge of how texts are constructed cohesively and use their judgment on the use of clipping in order to avoid overspecification (cf. also Schmitt, 1999: 306).

Specialist translators can in fact be viewed as experts in moving between system and use, between term banks or termbases, on the one hand, and texts, on the other, as well as drawing on running text for contextualized solutions. Future electronic terminology collections are likely to incorporate selected links to provide digital textual support to translators in their task, thereby further distinguishing the needs of translators from those of other users such as domain specialists and trainees.

Terracini, Aron Benvenuto (1886–1968)

C Parodi, University of California, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Aron Benvenuto Terracini, a Professor of Dialectology at the Italian Universities of Turin, Cagliari, Padova, and Milan and at the Argentinian University of Tucumán, was a member of the Accademia Nazzionale dei Lincei. He was one of the most outstanding scholars in dialectology, historical linguistics, and stylistics, as well as a pioneer in cultural and sociolinguistic studies. He studied in Paris with the dialectologist Jules Gillieron and with the philologist Antoine Meillet. During the Second World War Terracini was exiled from Italy to Argentina (1941–1946) because of his Jewish heritage.

As a dialectologist, he directed the Linguistic Atlas of Italy after Matteo Bartoli's death and the journal *Archivio glottologico italiano*. He wrote with Temistocle Franceschi a seminal work on dialect geography, *Saggio di un atlante linguistico della Sardegna* (1964). He combined dialectology and historical linguistics in his book *Pagine e appunti di linguistica storica* (1957), in which he analyzes the substrate of some Italian languages and dialects. He studied the Punic substrate of Latin and supported the hypothesis of a direct connection between the Southern Italian Greek dialects and Continental Greece, against the Byzantine hypothesis. He discovered pre-indoeuropean substrate elements in the Sardinian language by analyzing the etymology of place names. In his work on ancient Sardinian documents, 'Romanità e Grecità nei documenti piu antichi del volgare sardo' (1931), he proposed that Sardinian legal documents had to be written in the vernacular to be understood by the people because the population had limited knowledge of Latin and Greek.

The influence of the German idealistic linguistic school, mainly Karl Vossler, as well as Humboldt's concept of internal form of a language, were crucial in the development of Terracini's stylistic theory, as he presented it in *Analisi stilistica: teoría, storia problemi* (1966). His pioneer book on cultural studies, *Conflitti di lingue e di cultura* (1957), was conceived in Argentina during his exile. He published the first version in Spanish in 1951, but later on he revised it and translated it into Italian. The book is devoted to the study of language contact from both the microlinguistic and macrolinguistic points of view. He deals with issues such as language death, bilingualism, language policy, linguistic prestige, translation, and transcultural relations. He perceives language selection from bilingual into monolingual situations as a kind of mental translation in which one language is adopted. He considers translation as a cultural event in which the translator must create a personal differential grammar. He argues against positivism proposing nonmechanic subjective solutions to cultural innovations by individuals. According to Terracini, the dialogic relationship between nature and culture prompts a language to grow culturally.

Tesnière, Lucien Valerius (1893–1954)

K-Å Forsgren, Umeå Universitet, Umeå, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Lucien Valerius Tesnière (see Figure 1), French linguist, slavist, and grammarian, was regarded as the founder of dependency (valence) grammar. He was born in Mont-Saint-Aignan (Seine Maritime) in 1893 and died in Montpellier in 1954.

Tesnière studied comparative linguistics and the Slavic, Germanic, Finnish-Ugrian, and Celtic languages in Paris, Leipzig, and Vienna. In Leipzig he became a member of the linguistic school of Prague, introduced by N. S. Troubetzkoy. He worked as a teacher in Ljubljana and Strasburg. In 1937 he was appointed professor of linguistics in Montpellier, where he remained for the rest of his life.

Tesnière has found a place in the history of linguistics because of his syntactic theory, or the dependency or 'valence' theory that was posthumously published in *Éléments de syntaxe structurale* (1959), originally an attempt to simplify grammar for didactic purposes. Tesnière was critical of traditional grammar, finding it too complicated and comprehensive. He also rejected the subject and predicate as main constituents of the clause, which he regarded as an inadequate rest of Aristotelian logic in traditional grammar.

Tesnière's system is founded on a basic concept, 'connexion.' This simply means the connection of words in a clause, which presents itself to the ear as a 'linear order' extended in time. Quite different is the 'structural order,' which means the hierarchic relation between words. The clause *Alfred parle* ('Alfred is speaking') is a line of words, but to form a clause there must also be a meaningful connection between them. One word is dependant on the other, in this case, *Alfred* on *parle*. In a clause, the finite verb (if there is one) always has the highest rank. All the other words depend on the verb, and then on each other, in a hierarchic chain. Two other principal relations between the words of a clause are 'junction,' coordination with or without conjunctions, e.g., *Alfred et Bernard tombent* ('Alfred and Bernard are falling') and *Veni, uidi, uici*, respectively and 'translation,' e.g., *le livre de Pierre* ('Peter's book'), *un livre intéressant* ('an interesting book'), i.e., the hierarchic structure of phrases with or without prepositions. Tesnière compared the role of the verb in a clause to the valence of an atom: it determines the number of 'actants' (governed or closely connected words), which normally varies from zero ([*il*] *pleut*, 'it rains') to three (*Alfred dit bonjour à Charles*, 'Alfred said good morning to Charles'), thus corresponding to the notion of valence in chemistry. Not so closely connected are the 'circonstants,' usually adverbials (*Alfred part demain à midi*, 'Alfred leaves tomorrow at noon'). Tesnière was the first to use a tree diagram ('stemma') to demonstrate these relations (see Figure 2).

Tesnière's system has had a great impact on today's syntactic theory. It has turned out to be compatible with other disciplines such as grammars based on formal logic as developed by G. Frege (verb – actants ≈ predicate – arguments), generative grammar, structural semantics, and lexicography. However, it also has problems, e.g., with the lack of compatibility between different levels, such as grammatical and semantic valence (cf. Storrer, 1992).

Tesnière is generally regarded as the inventor of dependence grammar. The fact is, however, that the basic idea can be found in German grammar of the 19th century. A very similar hierarchical clause structure (even the term *Dependenz* was used in the same way!) with the verb at the top was outlined in the grammars of M. W. Götzinger (1833), A. Lehmann (1833), F. Kern (1888), and others. Whether these were Tesnière's sources or not, it does not lessen his

Figure 1 Lucien Valerius Tesnière (with permission from Marie-Héléne Tesnière).

achievement, which in any case has by far surpassed the first versions.

Testimony as a Belief Source

A belief source is a cognitive process that takes certain characteristic mental states as input and yields the representational state of belief as output. In the broadest sense of interest to epistemologists, testimony may be understood as a belief source whose input and output consist, respectively, of (a) reception of another's report about the world and (b) belief in what is reported. As such, testimony has a wide variety of manifestations, ranging from the highly formal to the exceedingly mundane – from taking the word

Testimony as a Belief Source

A belief source is a cognitive process that takes certain characteristic mental states as input and yields the representational state of belief as output. In the broadest sense of interest to epistemologists, testimony may be understood as a belief source whose input and output consist, respectively, of (a) reception of another's report about the world and (b) belief in what is reported. As such, testimony has a wide variety of manifestations, ranging from the highly formal to the exceedingly mundane – from taking the word

Table 1 Belief sources

Salient input	*Cognitive process*	*Output*
Sensory experience of the world, e.g., having the visual impression of a chair over yonder	*Sensory perception as a belief source*	*New belief about the world*, e.g., believing that there is a chair over yonder
Old belief about the world, e.g., believing that Socrates is a man and that all men are mortal	*Inference as a belief source*	*New belief about the world*, e.g., believing that Socrates is mortal
Old belief about the world, e.g., believing that it was cold on Tuesday	*Retentive memory as a belief source*	*Old belief about the world*, e.g., believing that it was cold on Tuesday
Reception of another's report about the world, e.g., hearing another say that it's raining	*Testimony as a belief source*	*New belief about the world*, e.g., believing that it's raining

of a sworn witness in a legal trial to accepting the nutritional information on a box of cereal.

Reflection on the ubiquity of testimony in this broad sense highlights the importance of language for our representation of the world. Thus, compare testimony with such belief sources as sensory perception, inference, and retentive (as opposed to recollective) memory, which may be characterized roughly as in the first three rows of Table 1.

In the case of the nontestimonial belief sources, description of the salient input need not explicitly mention language. Regarding testimony as a belief source, however, the appeal to language is unavoidable. Reception of another's report about the world quite obviously involves some kind of grasp of another's linguistic act – another's saying that things are thus-and-so, for example – or the linguistic effects thereof, such as the written record of another's say-so. Simply put, much of what we believe about the world would be lost without testimony, and without language, testimony would be lost.

Testimony as a Knowledge Source

Reflection on the ubiquity of testimony also highlights the potential importance of language for our felicitous representation of the world. To many epistemologists, testimony plays a central role in affording us not only mere beliefs about but also knowledge of the way things are, where knowledge is distinguished from mere belief at least partly by virtue of requiring justification or derivation from a proper source. (No matter how firmly one believes that supernatural phenomena exist, for example, one's belief that they do fails to amount to knowledge if it is unjustified or derived from an unreliable belief source such as wishful thinking.) As social creatures, Reid (1764/1997: 193) claimed, "We receive the greatest and most important part of our knowledge by the information of others." Echoing the point, Chakrabarti (1994b: 965) notes that "[w]itnesses in law courts, trusted travelers, historians, scientists, dictionaries, radio news-readers, parents, and computers have told us that something is the case and consequently we have come to *know* that it is so."

Skepticism

This common view is by no means universally held. Locke (1689/1989: 58) considered that "[t]he floating of other men's opinions in our brains makes us not one jot the more knowing, though they happen to be true. What in them was science is in us opiniatrety." Similarly, Barnes (1980: 200), who acknowledges that "we all do pick up beliefs in [a] second hand fashion," expresses the "fear that we often suppose that such scavenging amounts to knowledge." That, he claims, "is only a sign of our colossal credulity: [testimony] is a rotten way of acquiring beliefs, and it is no way at all of acquiring knowledge."

Skeptics such as Locke and Barnes insist that the most we can get when it comes to the connection between testimony and our representation of the world is the last row of Table 1: Testimony, in their view, can at best generate mere beliefs about the world – that is, beliefs that fail the justification or derivation-from-a-proper-source requirement on knowledge. Others, such as Reid and Chakrabarti, insist that the last row frequently describes a knowledge source: for them, what falls in the output box is often new knowledge of the world.

Even if we grant the importance of testimony for a felicitous representation of the world, we may well wonder how it works. Here, there are three questions to be distinguished. First, how more fully are we to understand the salient input to testimony if it is indeed to be understood as a knowledge source? Second, what, if anything, must be added to the salient input to get the total input to testimony as a knowledge source? Third, how are we to understand the cognitive process that leads from the total input to new knowledge of the world?

Perception and Understanding

Regarding the first question, there is little doubt that sensory perception is involved: In receiving another's report about the way things are, one

Table 2 Reductionist model of testimony as a knowledge source

Input	*Cognitive process*	*Output*
(a) Knowledge, acquired through sensory perception of understood linguistic acts (or their effects), that another has reported something about the world, and (b) knowledge that the reporter is trustworthy with respect to his or her report about the world	Inference from input to output	New knowledge of the world

Table 3 Anti-reductionist model of testimony as a knowledge source

Input	*Cognitive process*	*Output*
Knowledge, acquired through sensory perception of understood linguistic acts (or their effects), that another has reported something about the world	Causation of output by input	New knowledge of the world

comes to know that another has reported that things are thus-and-so on the basis of visual, auditory, etc. experience of the physical items that encode the report. However, bare sensory perception does not suffice. Both the monolingual Japanese hearer and the Anglophone hearer might equally perceive through their senses a speaker's auditory deliverance 'I'm tired today,' even though only the latter may count as receiving the speaker's report that he or she is tired today, because only the latter may understand the meaning of the perceived deliverance. Generally, then, the salient input to testimony as a knowledge source amounts to knowledge, acquired through sensory perception of an understood linguistic act (or its effects), that another has reported that things are thus-and-so.

Reductionism and Anti-reductionism

The second and third questions bring us to the heart of the most prominent issue in epistemologists' attempt to understand the nature of testimony as a knowledge source, viz. the reductionist/anti-reductionist debate. Whereas reductionists (Fricker, 1987; Hume, 1777/1995) maintain that testimony as a knowledge source reduces across the board to a species of inference, anti-reductionists (Burge, 1993; Chakrabarti, 1994a; Coady, 1992; McDowell, 1994; Reid, 1764/1997; Strawson, 1994) demur.

The kind of inference to which testimony as a knowledge source reduces, according to reductionists, is inference from the salient input together with knowledge of the trustworthiness of the reporter with respect to what he or she has reported. Hence, reductionists' answer to the second question is that knowledge of the trustworthiness of the reporter must be added to the salient input to get the total input to testimony as a knowledge source. Their answer to the third question is that we are to understand the cognitive process leading from testimony's total input to its output as one of inference. These answers jointly present a model of testimony as a knowledge source that is roughly captured in Table 2.

Anti-reductionists' answer the second question, in contrast, holds that in many cases nothing must be added to the salient input to get the total input to testimony as a knowledge source. Their response to the third question is that the cognitive process leading from testimony's total input to its output is better thought of simply along the lines of causation in general, since inference in particular is not required (although it may in some cases be present). Thus, the anti-reductionist opts for something like the model given in Table 3.

(Stepping outside of the recipient's cognitive processes, it should be noted, the anti-reductionist requires certain external conditions to be satisfied for the output of testimony as a knowledge source to amount to knowledge. Like the reductionist, he or she requires that what is reported be true; he or she further requires that the reporter in fact be trustworthy with respect to his or her report, even though the recipient need not know that he or she is trustworthy.)

Reductionists claim that the anti-reductionist model lends itself all too easily to something like epistemic gullibility and hence fails to serve as a plausible model for testimony as a legitimate knowledge source. Anti-reductionists point to cases in which it is supposedly clear that the reductionist model does not apply, most notably those involving young children's acquisition of linguistic knowledge. (Such acquisition seems to be in large part testimonial, but, say anti-reductionists, it cannot with any plausibility be regarded as typically involving inference from knowledge of the trustworthiness of reporters.) Considerations of this sort have tended to shift the focus of the reductionist/anti-reductionist debate to the question of how to understand testimony as a knowledge source for mature cognitive agents, already possessed of the sort of linguistic knowledge just mentioned (Fricker, 1994, 1995).

Summary

Testimony is undeniably a major source of our beliefs about the world, a fact that underscores the centrality of language for our representational capacities. Many maintain that testimony is also a major source of our knowledge of the world, a contention that implies the centrality of language for our felicitous representational capacities. Even granting this contention, however, there is considerable debate about the nature of testimony. Clearly, it involves knowledge, through sensory perception of understood linguistic acts (or their effects), that another has reported that things are thus-and-so. In the reductionist model, it reduces across the board to inference from such knowledge and from knowledge of the reporter's trustworthiness with respect to his or her report. In the anti-reductionist model, no such reduction obtains.

Communication Through Text and Discourse

People use language to communicate. Language users communicate through discourse. Sometimes, utterances of one word ('John!' 'Okay.' 'Stop!') or one sentence ('I declare the games opened') suffice to get the message across, but usually language users communicate through a connected sequence of minimally two utterances, i.e., discourse. The importance of the discourse level for the study of language and linguistics can hardly be overestimated: "Discourse is what makes us human" (Graesser *et al.*, 1997). It is not surprising, therefore, that the study of text and discourse has become an increasingly important area over the last decades, both in linguistics and psychology.

The term 'discourse' is used as the more general term to refer to both spoken and written language. The term 'text' is generally used to refer to written language. This article focuses on text. Although spoken and written discourse have crucial characteristics in common, the linguistic traditions of the study of written and spoken discourse are very different. 'Monological texts' are traditionally studied in areas such as stylistics, text linguistics, and psycholinguistics, often based on rather specific linguistic analyses and regularly using a quantitative methodology. Summary

Testimony is undeniably a major source of our beliefs about the world, a fact that underscores the centrality of language for our representational capacities. Many maintain that testimony is also a major source of our knowledge of the world, a contention that implies the centrality of language for our felicitous representational capacities. Even granting this contention, however, there is considerable debate about the nature of testimony. Clearly, it involves knowledge, through sensory perception of understood linguistic acts (or their effects), that another has reported that things are thus-and-so. In the reductionist model, it reduces across the board to inference from such knowledge and from knowledge of the reporter's trustworthiness with respect to his or her report. In the anti-reductionist model, no such reduction obtains.

Communication Through Text and Discourse

People use language to communicate. Language users communicate through discourse. Sometimes, utterances of one word ('John!' 'Okay.' 'Stop!') or one sentence ('I declare the games opened') suffice to get the message across, but usually language users communicate through a connected sequence of minimally two utterances, i.e., discourse. The importance of the discourse level for the study of language and linguistics can hardly be overestimated: "Discourse is what makes us human" (Graesser *et al.*, 1997). It is not surprising, therefore, that the study of text and discourse has become an increasingly important area over the last decades, both in linguistics and psychology.

The term 'discourse' is used as the more general term to refer to both spoken and written language. The term 'text' is generally used to refer to written language. This article focuses on text. Although spoken and written discourse have crucial characteristics in common, the linguistic traditions of the study of written and spoken discourse are very different. 'Monological texts' are traditionally studied in areas such as stylistics, text linguistics, and psycholinguistics, often based on rather specific linguistic analyses and regularly using a quantitative methodology. By contrast, 'dialogical discourse' has long

been the arena of conversation analysis and sociolinguistics, often focused on qualitative interpretations of individual conversations in context. Over the last 10 years, this situation has begun to change. With the growing availability of spoken corpora and the growing insight that the study of spoken and written discourse should be related because they complement each other (Chafe, 1994), the linguistic study of discourse is becoming less and less restricted to one medium. See, for instance, the overview by Ford *et al.* (2001), who relate linguistic subdisciplines such as grammar and the study of conversation.

A text is more than a random set of utterances: it shows connectedness. A central objective of linguists working on the text level is to characterize this connectedness. Linguists have traditionally approached this problem by looking at overt linguistic elements and structures, thereby characterizing it in terms of cohesion (Halliday and Hasan, 1976; *see* **Cohesion and Coherence: Linguistic Approaches**). By this view, connectedness is localized in the text itself because of explicit linguistic clues, such as pronouns referring to earlier mentioned subjects (cohesion type: *reference*), e.g., *he* refers to *bird-watcher* in (1); or conjunctions, such as *because* in (2) (cohesion type: *conjunction*), which express a causal relation.

(1) The bird-watcher had a great day. He observed a kingfisher and a group of 70 cranes.

(2) The bird-watcher had a great day because he observed a kingfisher and a group of 70 cranes.

(3) The bird-watcher had a great day. A kingfisher and a group of 70 cranes were in the area.

Influential as the cohesion approach has been, the interdisciplinary field of text linguistics and discourse studies is nowadays dominated by the 'coherence' approach: the connectedness of text is considered a characteristic of the mental representation rather than of the text itself (*see* **Cohesion and Coherence: Linguistic Approaches** and **Coherence: Psycholinguistic Approach**). The main reason is probably that a sequence of sentences like (1) or (2) is still interpreted as a perfectly normal piece of text if the cohesive elements of reference and conjunction are absent, as in (3). Hence, the connectedness is not dependent on these overt markers. This does not imply, however, that the linguistic elements signaling text coherence are unimportant.

Although coherence phenomena are of a cognitive nature, their reconstruction is often based on linguistic signals in the text itself. These linguistic expressions are considered 'processing instructions' to language users. For instance, referential expressions, such as pronouns and demonstratives, are used in such a way that interpreters can systematically recover the referential coherence (*see* **Accessibility Theory** and **Discourse Anaphora**). Similarly, connectives (*because*, *however*) and (other) lexical markers of relations, such as cue phrases (*On the one hand*, *on the other hand*) and signaling phrases (*The problem is . . . A solution might be . . .*), make the meaning relations between text segments explicit (*see* **Connectives in Text**). In recent years, the relationship between the linguistic surface code, on the one hand, and aspects of the text representation, on the other hand, has become a crucial research issue in the interdisciplinary field of text linguistics and discourse studies (cf. Gernsbacher and Givón, 1995; Sanders and Spooren, 2001; Graesser *et al.*, 2003).

Text

It follows from the discussion above that, in this article, we consider a text to be a monological stretch of written language that shows coherence. The term 'text' derives from the Latin verb *texere* 'to weave' (hence the resemblance between the words 'text' and 'textile'). But what is it that makes a text a text? This question has been at the center of attention of the fields of discourse studies and text linguistics, especially since the 1970s.

Meaning Rather than Form

In the area of syntax – 'sentence analysis' – the principled discussion on the question of whether syntax is an autonomous and purely formal level of representation is still going on, especially with the recent rise of cognitive linguistics (cf. Langacker, 1986; Jackendoff, 1996) (*see also* **Cognitive Linguistics**). At the discourse level such a discussion is nowadays absent. In the pioneering years of text linguistics, scholars like van Dijk (1972) and Petöfi and Rieser (1973) attempted to describe texts as a string of sentences within the framework of generative grammar. Analogous to the way in which sentence grammars described sentences in terms of their constituents, texts were seen as constituted by sentences. In generative grammar, a sentence is the result of rewriting rules of the form: $S \rightarrow NP + VP$.

In 'text grammars,' a text was regarded as consisting of sentences: $T \rightarrow S1 \ldots Sn$. Similarly, the top of hierarchical text representations was formed by a T (for 'text'), analogous to the S for sentence in generative sentence representations. In psychology, so-called 'story grammars' were developed in the late 1970s (Thorndyke, 1977; Rumelhart, 1977). According to such representations, a 'story' consists of a

setting ("Once upon a time, there was a little girl who lived in the woods with her parents. She was called Little Red Riding Hood.") and an 'episode' ("One day, her mother asked her to bring some food to grandmother ...") and, with the help of the same type of rewriting rules, episodes can in turn be represented as a combination of an 'event' ("Why do you have such a big mouth? she asked.") and a 'reaction' ("The wolf jumped out of bed and ate her."):

Story → setting + episode

Episode → event + reaction

Several scholars have argued that the analogy with sentence grammar is not convincing, among them Brown and Yule (1983) and Wilensky (1983):

> ... while our intuition of 'sentencehood' is a clearly linguistic notion, our intuition of 'storiness' most certainly is not [...]. the notion of 'Story' refers to actions, events, goals, or other mental or conceptual objects. In other words, our intuitions about stories are closer to our intuitions about the meanings of sentences than they are about they are about sentences themselves (Wilensky, 1983: 580).

And indeed, ever since Halliday and Hasan (1976), Hobbs (1979), and van Dijk (1977), it is widely accepted that purely formal or syntactic principles play a far smaller role at the discourse level. It is hard, for instance, to make much sense of the idea of a structurally 'well-formed' but semantically anomalous text. There is a consensus that the well-formedness of a discourse is primarily to do with its meaning – more specifically, with the question of whether the meanings of its component segments can be related together to form a coherent message.

What Makes a Text a Text?

What, then, are the crucial characteristics of text? At present, the dominant stance is that 'coherence' explains best the connectedness shown by texts. Coherence is considered a mental phenomenon; it is not an inherent property of a text under consideration. Language users establish coherence by relating the different information units in the text.

Generally speaking, there are two respects in which texts can cohere (Sanders and Spooren, 2001):

- 'Referential coherence': smaller linguistic units (often nominal groups) may relate to the same mental referent throughout the text (*see also* **Discourse Anaphora**); or
- 'Relational coherence': text segments (most often conceived of as clauses) are connected by coherence relations, such as cause-consequence, between them (*see also* **Clause Relations**).

Both coherence phenomena under consideration – referential and relational – have clear linguistic indicators that can be taken as processing instructions. For referential coherence, these are anaphoric devices such as pronouns, and for relational coherence these are connectives and (other) lexical markers of relations.

Ever since the seminal work of linguists such as Chafe (1976) and Prince (1981), both functional and cognitive linguists have argued that the grammar of referential coherence can be shown to play an important role in the mental operations of connecting incoming information to the existing mental representations. For instance, referent NPs are identified as either those that will be important and topical, or as those that will be unimportant and nontopical. Hence, topical referents are persistent in the mental representation of subsequent discourse, whereas the nontopical ones are nonpersistent. In several publications, Ariel (1988, 2001) argued that regularities in grammatical coding should indeed be understood to guide processing. She studied the distribution of anaphoric devices and suggested that zero anaphora and unstressed pronouns cooccur with high 'accessibility' of referents, whereas stressed pronouns and full lexical nouns signal low accessibility. This cooccurrence can easily be understood in terms of cognitive processes of activation: high-accessibility markers signal the **default** choice of continued activation of the current topical referent. Low-accessibility anaphoric devices, such as full NPs or indefinite articles, signal the terminated activation of the current topical referent and the activation of another topic (*see* **Accessibility Theory**).

'Centering theory' (see Walker *et al.*, 1998 for an overview) makes explicit and precise predictions about the referent that is 'in focus' at a certain moment in a discourse. It even predicts that the degree of text coherence is determined by the extent to which it conforms to 'centering constraints.' Given a clause in which referential antecedents are presented, centering theory predicts the likelihood that an antecedent will be a central referent – which is 'in focus' – in the next clause. The salience of a discourse entity is determined by a combination of syntactic, semantic, and pragmatic factors, such as grammatical role (subject or not), expression type (zero, pronoun, or NP), and discourse topic-hood. Several processing studies have demonstrated the 'psychological reality' of linguistic indicators of referential coherence (see Garrod and Sanford, 1994, and Sanford and Garrod, 1994, for an overview; *see also* **Discourse Processing**).

We now turn to (signals of) 'relational coherence.' 'Coherence relations' are often taken to account for the connectedness in readers' cognitive text

representation (cf. Hobbs, 1979; Sanders *et al.*, 1992). They are also termed 'rhetorical relations' (Mann and Thompson, 1988; *see* **Rhetorical Structure Theory**) or 'clause relations' (*see* **Clause Relations**). 'Coherence relations' are meaning relations connecting, at a minimum, two text segments. A defining characteristic for these relations is that the interpretation of the related segments needs to provide more information than is provided by the sum of the segments taken in isolation (Sanders *et al.*, 1992). Examples are relations like 'cause-consequence,' 'list,' and 'problem-solution.' These relations are conceptual and they can, but need not, be made explicit by linguistic markers, so-called connectives (*because*, *so*, *however*, *although*) and lexical cue phrases (*for that reason*, *as a result*, *on the other hand*) (*see* **Connectives in Text**).

In the last decade, much research in relation semantics and pragmatics has focused on the question of how to taxonomize or classify the set of coherence relations (Hovy, 1990; Knott and Dale, 1994; Pander Maat, 1998; Redeker, 1990; Sanders, 1997). The main reason for this interest is the cognitive interpretation of coherence relations: if they are to be considered as cognitive mechanisms underlying discourse interpretation, it is attractive to find out which more general principles are involved in relation interpretation. While work on the hierarchical classification of discourse relations goes back at least as far as Grimes (1975) and Halliday and Hasan (1976), the idea that a small number of reasonably orthogonal primitives is responsible for the differences amongst coherence relations is more recent. Sanders *et al.* (1992) defined the 'relations among the relations,' relying on the intuition that some coherence relations are more alike than others, and that the set of relations can be organized in terms of more primitive notions, such as polarity and causality. Several types of evidence in favor of such an organization were produced, varying from experiments in which text analysts judged relations (Sanders *et al.,* 1992, 1993; Sanders, 1997), to research on the acquisition order of connectives (Evers-Vermeul, 2005) and processing studies indicating how different coherence relations result in different representations (Sanders and Noordman, 2000; *see also* **Connectives in Text**). In such an account of coherence, connectives and other lexical signals are seen as 'processing instructors.' And indeed, experimental studies on the role of connectives and signaling phrases show that these linguistic signals affect the construction of the text representation (cf. Millis and Just, 1994; Noordman and Vonk, 1997).

In sum, it can be concluded that there is compelling evidence, from both linguistic and psycholinguistic studies, in favor of the view that referential and relational coherence are crucial principles, which make a set of sentences a text.

Text Analysis

Now that we have an idea of what a text is, we can define 'text analysis' as the systematic dissection of a textual unity in its constituent parts and the study of those parts in relation to each other. By consequence, text analysis focuses on the linguistic elements present in the text. Texts may be analyzed with different aims and from several perspectives.

A first text-analytic research goal is of a theoretical nature. It concerns the further development of linguistic theory at the discourse level: how are texts structured? There are now several well-established theories that propose mechanisms by which the meaning of individual sentences can be constructed, but the situation with entire texts is different. Text analysis is of crucial importance to the further development of text linguistics.

A second aim is to provide insight into the cognitive processes of reading and writing, or in the text representation that language users have of a text. In reading research, the role of text structure is an important research topic in which text analyses are used to model both the text structure and the representation that readers make of it (see previous paragraph). In writing research, the role of text analysis has received less attention for a long time, even though Bereiter and Scardamalia (1987) argued for the interaction between psychological models and text linguistic research. They pointed to a deficiency in studies of writing and argued that text analysis had a large role to play in discovering the implicit rules of composition.

A third aim is of a computational linguistic nature: the development of computational models of automatic summarization, text generation, and interpretation. Here, the analysis of natural texts should provide the rule system to arrive at such computational models. Although some theories and models discussed in the sections to follow were explicitly developed in the context of such a computational enterprise (such as **Rhetorical Structure Theory**), computational text analyses are not discussed here (*see* **Natural Language Processing: Overview**).

A fourth aim is the evaluation of text quality in the context of written composition and document design. A text analysis can provide the basis for a comparison of similar texts, enabling researchers to compare the writing ability of the authors (Cooper, 1983). In document design, text analysis can predict areas where readers may have difficulties and where

revision is imperative. It is also used to investigate the relationship between text structure and the successful layout of various documents, even multimodal ones (Delin and Bateman, 2002).

From what perspectives do text analysts try to catch the 'meaning' in text? A first division is that between content-oriented and structure-oriented approaches. 'Content-oriented' approaches to text analysis uncover what an individual text is 'about,' either by starting from the smallest building blocks (propositions) or by characterizing texts on a more global level: the topics and subtopics that are covered. 'Structure-oriented' approaches uncover the meaning relations between the textual building blocks, such as causal, contrastive, and additive relations, but also referential relations. Some approaches provide analytic models that allow for a hierarchical representation representing the whole text in such terms.

Content-Oriented Approaches

Micro- and Macrostructure In the context of a psychological model of text processing, Van Dijk and Kintsch (1983) distinguished between three aspects of text representation: 'microstructure,' 'macrostructure,' and 'superstructure' (*see* **Macrostructure**). Superstructures – representing the global structure that is characteristic of a text type – will be discussed in the section on structure-oriented approaches. Micro- and macrostructure concern the **content** of a text. The basic building blocks of these representations are 'propositions,' i.e., a unit of meaning that consists of a predicate and connected arguments. For instance, the proposition underlying sentence (4) would be (4'), where *see* is the predicate and *he* and *kingfisher* are the arguments.

(4) he sees a kingfisher
(4') (see (he, kingfisher))

The microstructure is a network of propositions like these that represents the textual information in a bottom-up fashion, sentence by sentence. Building on earlier work, van Dijk and Kintsch (1983) presented an influential model of text comprehension, which predicted the information recalled best by readers. For the purpose of text analysis, it is important to focus on another component of the Van Dijk and Kintsch model: macrostructure. On the basis of the microstructure or 'text base,' a macrostructure can be built – an abstract representation of the global meaning structure that would reflect the gist of the text (*see* **Macrostructure**). This is achieved by applying macro-rules to the detailed meaning representation of the microstructure. 'Deletion,' 'generalization,' and 'construction' are such macrorules, which produce macro-propositions: the main ideas in the text (see especially van Dijk, 1980). This idea of producing the macrostructure on the basis of the details of the microstructure is certainly appealing. The results of some experimental processing studies seem to show that macrostructures can predict recall and summarization results: Propositions present in the macrostructure are remembered better than propositions that are 'only' present in the microstructure (Graesser, 1981). Arguably, the theoretical and empirical status of this part of the van Dijk and Kintsch theory is less clear than the microstructure part. This was probably a result of the fact that macrorules were underspecified. In addition, it is not always easy to identify linguistic signals of macropropositions at the surface level of the text, even though titles, headings, abstracts, and topical sentences are mentioned as signalling macropropositional ideas. In recent years, Kintsch (1998) and others have argued that macrostructures can be derived from texts by using 'latent semantic analysis' (*see* **Latent Semantic Analysis**). Here, the meaning of sentences is represented by a vector in a high-dimensional semantic space. Vectors that relate most to the rest of the text can be identified as macropropositions.

Theme and Thematics 'Thematics' is the interdisciplinary study of 'about-ness' in text (*see* **Thematics**). The notion of 'theme' refers to the main idea or topic of the text. For instance, a text can be about a kingfisher or about an ornithologist having a great day. The study of theme has been popular in literary studies. Thanks to the involvement of text linguistics and stylistics, the study of linguistic cues that create thematic meaning has become increasingly important (Louwerse and Van Peer, 2002). For instance, formulations and stylistic figures also emphasize the thematic meaning of a text.

However, regular aspects of formulation, such as the linear order of the information in clauses and sentences, can also contribute to the identification of the theme. A typical linguistic aspect studied in more detail is the way in which the first position in a clause has a special textual status. The terminology is somewhat confusing here, because linguists refer to the information provided in this position with the term 'theme,' whereas any information following this local theme is called 'rheme' (*see* **Theme in Text**). The opening positions of clauses often contain information that guides the reader in constructing a picture of the text as a whole. In linguistics, and especially in systemic functional grammar, sequences of theme–rheme are studied, resulting in patterns of thematic development.

Structure-Oriented Approaches

Most linguistic methods of text analysis focus on the general properties of text structure, abstracting away from the specific content of individual texts. Accounts of text structure usually pay attention to

1. the meaning of the left-right relations between text segments, where the analysis is based on relational and referential coherence; and
2. the hierarchical structure of the text, which accounts for the intuition that the information that is ordered higher in a tree-like representation is more important than the lower information.

Superstructure van Dijk and Kintsch's (1983) model included micro- and macrostructures, which resulted in a representation of the text content, as was discussed above. The third element in their model is the 'superstructure,' which "provides a kind of overall functional syntax for the semantic macrostructures" (van Dijk and Kintsch, 1983: 242). It is the conventional, hierarchical form in which the content of the macrostructure is presented. An example of such a superstructure is that of the type 'news discourse,' in which superstructural categories are distinguished, for example, *headlines, lead, context, event*. Superstructural categories are typically of a global nature in that they organize larger chunks of text rather than consecutive sentences. In addition, a superstructure analysis proceeds top-down: it starts from the highest text level. Superstructures for several other conventional text types were developed, among them the 'Experimental article.' There seems to be a clear parallel here with text type and genre: it would seem logical to expect that stereotypical text types can be characterized in terms of a superstructure (*see* **Genre and Genre Analysis**). Therefore, a text analysis in terms of superstructures is text type-specific by definition.

Clause Relations, Coherence Relations, and Discourse Patterns By contrast, a text analysis based on clause or coherence relations would be generally applicable, independent of text types. It proceeds bottom-up, starting from consecutive clauses. One common relation is called 'problem-solution' or 'solutionhood' (*see* **Problem-Solution Patterns**). See examples (5) and (6).

(5) I'm hungry. Let's go to the Fuji Gardens.

(6) What if you're having to clean floppy drive heads too often? Ask for Syncom diskettes, with burnished Ectype coating and dust absorbing jacket liners.

Mann and Thompson (1986, 1988) treated solutionhood as simply one of the relations, where others have argued that solutionhood was more complex than that (Grimes, 1975; Hoey, 1983; Sanders *et al.*, 1993): "Both of the plots of fairy tales and the writings of scientists are built on a response pattern. The first part gives a problem and the second the solution" (Grimes, 1975: 211). On the basis of clause relations, more complex structures can be built: a 'discourse pattern' (Hoey, 1983) or a 'response pattern' (Grimes, 1975). Hoey (1983) argued that a recurrent combination of clause relations can organize a substantial text fragment, or even a whole text. See the illustrating example from Hoey (1983: 35):

(7) (i) I was on sentry duty.
(ii) I saw the enemy approaching.
(iii) I opened fire.
(iv) I beat off the attack.

Hoey provided several paraphrase tests to recognize the clause relations on which the pattern is based: 'instrument-achievement' with '(iii) thereby (iv),' 'by (iii) . . . ing,' and '(iii) by this means (iv)' (Hoey, 1983: 39–41); and 'cause-consequence' 'because (ii), (iii)' and '(ii) therefore (iii)' (Hoey, 1983: 41–42). Paraphrase tests like these are often a great help for inexperienced text analysts, who find it hard to determine the exact relationship expressed between text segments.

This heuristic to identify discourse patterns is an outstanding example of a text-analytic method in the field of clause and coherence relations. The research in this field discussed earlier in this section has probably been more important for the identification of coherence relations and for the theoretical issues discussed earlier (the nature of coherence, taxonomies of relations, the linguistic expression and processing of relations). However, a very important account has not been discussed so far: rhetorical structure theory.

Rhetorical Structure Theory In the 1980s and 1990s, Mann and Thompson (see especially Mann and Thompson, 1988) presented 'rhetorical structure theory' (RST), a functional theory of text organization developed in the context of linguistics and cognitive science (*see* **Rhetorical Structure Theory**). At the heart of RST are the so-called 'rhetorical relations,' similar to clause or coherence relations, and including relations like 'cause,' 'elaboration,' and 'evidence.' The relations are defined in terms of conditions on the nucleus (the most important segment in a relation), on the satellite (which depends on the nucleus), and their combination, and in terms of the effect on the reader. Relations are identified between adjacent text segments (e.g., clauses) up to the top level of the

text. The top level of an RST tree organizes the text as a whole: a relationship that dominates the total text structure.

Rhetorical structure theory has proven to be a very useful analytic tool. One of its benefits is that it allows for a complete analysis of any text type: expository, argumentative, or narrative. The system has been applied to many real-life texts, among them newspaper articles, advertisements, and fundraising letters (Mann and Thompson, 1992). As a rule, an RST analysis starts with an inspection of the **entire** text. The analysis does not proceed in a fixed way; it proceeds bottom-up (from relations between clauses to the level of the text) or top-down (the other way around) or follows both routes (Mann *et al.*, 1992). The analysis results in a hierarchical structure that encompasses the entire text and has a label attached to each of its branches.

Although RST defines rhetorical relations in a fairly exact way, the assignment of a label is ultimately based on observed 'plausibility.' Four general constraints are the guidelines: 'completedness,' 'connectedness,' 'uniqueness,' and 'adjacency' (Mann and Thompson, 1988: 248–249). How the analysis actually proceeds is left to the intuitions of the analyst and is, in the end, a matter of text interpretation. Still, it has been shown that RST can be applied with a reasonable amount of consensus by expert text analysts (Den Ouden, 2004) and to a certain extent, RST analyses can even be produced automatically (Marcu, 2000).

Procedural Text Analysis Rhetorical structure theory requires a fair amount of text interpretation based on the analysts' overview of the text as a whole. This overview situation may not reflect the way in which writers produce texts. Spontaneously produced texts, especially, are the result of a more incremental process. Sanders and van Wijk (1996) developed 'procedures for incremental structure analysis' (PISA), which incorporates both ideas about written text production and insights from the text analytical literature, especially with respect to hierarchical aspects of text structure. The two texts in example (8) are taken from the PISA corpus. They were written by 12-year-old boys in response to a request to explain who Saint Nicholas is to someone who knows nothing about the subject. The texts are translated from Dutch in a rather literal way, preserving the original punctuation. For the analysis, texts were divided into segments, roughly corresponding to clauses. The hierarchical structures of the texts in (8a and 8b) are shown in Figures 1 and 2.

Figure 1 Hierarchical structure of an explanatory text, dominated by a sequence of actions. (Reproduced from Sanders T & van Wijk C (1996). 'PISA – a procedure for analyzing the structure of explanatory texts.' *Text, 16(1)*, 91–132 with permission by Elsevier.)

Figure 2 Hierarchical structure of an explanatory text, dominated by referential coherence. (Reproduced from Sanders T & van Wijk C (1996). 'PISA – a procedure for analyzing the structure of explanatory texts.' *Text, 16(1)*, 91–132 with permission by Elsevier.)

(8a) (1) Every year Saint Nicholas comes (2) that is on the 4th of December (3) That day he comes by steamboat (4a) When he arrives in the Netherlands (4) then everyone waves to him (5) At night (5a) when it is pitch-dark (5) Saint Nicholas rides over the roofs with Black Peter (6) and throws lots of presents through the chimney (7) while the children sing a song (7a) such as: Sinterklaas kapoentje . . . (8) Saint Nicholas gives lots of presents (9) but he always gets something in return (10) That is either a carrot for the horse or a bit of water, also for the horse (11) On the fifth of December Saint Nicholas really has his birthday (12) on that day he brings the presents (13) and then he leaves again. (14) He also looks into the red book with the cross on it. (15) There it says whether you have been naughty or not (16a) When Saint Nicholas leaves again (16) the children sing Bye bye Saint Nicholas.

(8b) (1) Saint Nicholas is an old man (2) He has a white-grey beard (3) He has a steamboat with a lot of little black men (4) They are called Black Peter (5a) When it is the fifth of December (5) the time has come. (6) The day of Saint Nicholas is a Big Festival. (7) The Peters have a birch. (8) A birch is a bundle of swishing branches. (9) They also have a sack (10) that is a kind of wool and a shape. (11) The children in all villages and towns got ginger-nuts. (12) And ginger nuts are four-sided blocks, with sugar. (13) That is candy (13a) that children like. (14) Well, Saint Nicholas is an old man, with white hair. (15) He wears a red robe. (16) And wears a sort of shirt. (17) He also has a whitish grey. (18) A grey is a horse. (18a) (noble animal) (19) Just now I was talking about a steamboat. (20) A steamboat is a big ship, (21) a steamboat often has got a big funnel (21a) from which the steam comes. (22) The children sing songs on the fifth of December, (23) that is because there is a big feast.

The texts in (8) illustrate two different ways of arranging information in an explanatory text. The first one follows the **temporal order** of events: first he arrives, then, at night, he rides over the roofs. On December 5, he has his birthday and the children get presents. And then he leaves and the children sing to him. By contrast, the writer of the second text solves the problem of explanation by focusing on the topic of the text. He mentions all kinds of **properties** of Saint Nicholas in a rather associative way: He is old, has a white beard, a steamboat, etc.

Clearly, these two texts differ in their global structure. The first one is dominated by an 'action-line,' a temporal sequence of actions, and the second one is dominated by a 'property-line,' a list of characteristics of the topic. Text structures like these may reflect the way in which the writer has organized the information during the production of the text. For example, the first text can be produced by running through episodic memory; the actions or events are mentioned in temporal succession and the text ends with the closing of an episode. The second text, on the other hand, is probably produced by searching semantic memory in an associative way. It resembles brainstorming; it lists information related to the topic, which is potentially relevant to explain it.

In a series of publications, it has been argued that the product of this text-analytical method is cognitively interpretable because it correlates with pause time distribution during writing (Schilperoord, 1996; Sanders and Schilperoord, 2005) and explains writing development (van der Pool, 1995), sentence-combining results, and problems during writing (van Wijk and Sanders, 1999). The generalizability of an incremental and procedural approach like this is limited; it has specifically been shown to be successful for spontaneously written explanatory texts and judicial letters that were produced without much planning.

Conclusion and Further Research

There are several interesting developments for the research agenda in the years to come. Before we go into detail, a general methodological remark seems in order. Text analyses of corpora of natural language texts have a crucial role to play in text linguistics and discourse studies, because the development of theoretical models of discourse phenomena needs to proceed in interaction with the study of the (sometimes very complex) reality of natural language in use (cf. Emmott, 1997).

Let us now focus on some specific issues that follow from our analysis of the state-of-the-art in the preceding sections. A first important issue is the linguistics/text linguistics interface. There are clear rapprochements between grammarians, (formal) semanticists, and pragmaticists on the one hand and text linguists on the other hand (Sanders and Spooren, in press). Questions to be asked are: what is the relationship between information structuring at the sentence level and at the discourse level? How do factors such as tense, aspect, and perspective influence discourse connections (Lascarides and Asher, 1993; Oversteegen, 1997)? For instance, discourse segments denoting events that have taken place in the past (*The bird-watcher saw a small blue bird near the river. It was a kingfisher*) will typically be connected by coherence relation of the content type, whereas segments in the present/future, which contain many evaluations or

other subjective elements (*Here is that small blue bird again. It must be a kingfisher*), are prototypically connected by epistemic or argumentative relations (*see* **Connectives in Text** and **Evaluation in Text**). This correlation, in turn, should be studied in connection with issues like perspective and subjectivity (Sanders and Redeker, 1996; Pander Maat and Sanders, 2001).

A second obvious issue is the relationship between the principles of relational and referential coherence. Clearly, the two types of principles both provide language users with signals during text interpretation. Theses signal are taken as instructions for how to construct coherence. Therefore, the principles will operate in parallel, and they will influence each other. The question is: How do they interact? Consider a simple example.

(9) John congratulated Pete on his excellent play.
  (a) He had scored a goal.
  (b) He scored a goal.

At least two factors are relevant for the solution of the anaphor *he* in (a/b): the aspect of the sentence, and the possible coherence relations that can be inferred between sentences. Part (9a) has perfect tense, and at the discourse level, the interpretation of one coherence relation is obvious – namely the backward causal relation 'consequence-cause.' The tense of (9b) is imperfect, and at the discourse level several coherence relations can exist, including 'temporal sequence' (of events) and 'enumeration/list' (of events in the game). Hence, the resolution of the anaphor-antecedent relation seems to be related to these two factors. In (9a) *he* must refer to Pete; in (9b), both antecedents are possible: John or Pete. How do aspect and the coherence relation interact in the process of anaphor resolution? And: Is the anaphor resolved as a consequence of the interpretation of the coherence relation? Questions like these were already addressed in the seminal work of Hobbs (1979) and recently taken up again in a challenging way by Kehler (2002). Text analysis of natural texts has a large role to play here: How often do ambiguities like these actually show up in text? What are the heuristics apparently used by language users?

A third issue is the further characterization of genres and text types in terms of their text structure. Genre and text type are both frequently used concepts (*see* **Genre and Genre Analysis**) that are often not defined in articulate text-internal characteristics (see Virtanen, 1992). Now that text-analytic models like RST are available and the theory of different types of coherence relations has matured, it is high time that structural analysis of real-life corpus texts show whether text types differ systematically in their text structure. In a first corpus study (Sanders, 1997), such a correlation was indeed found. 'Informative texts' (in which the writer's goal is to inform the reader about something) were compared to 'expressive texts' (in which the writer's goal is to express his or her feelings and attitudes) and 'persuasive texts' (in which the writer's goal is to persuade the reader of something). It was shown that persuasive texts were indeed dominated by more subjective relations, used by the writer to put forward the argument, whereas encyclopedic texts were shown to be informative because their structure was dominated by more objective relations, in which the writer simply described the content area. The realization of this type of text-analytic work on a larger scale would make notions of text type more concrete, but it also provides an example of the way in which text structural characteristics could be operationalized for the further study of language use, on a par with many stylistic text characteristics.

A fourth and final issue concerns the role of text analysis in text evaluation and document design. Many teachers believe that the best and the worst essays written in class differ in organization. The best one is structured clearly, whereas the worst one is hard to follow. Traditionally, there are few results from research to underpin observations like these. However, this situation has recently improved. For instance, children's explanatory texts showing continuity might be judged better than texts that show discontinuities (Sanders and van Wijk, 1996; van Wijk and Sanders, 1999).There are at least two cognitive reasons to link structure and judgments about text quality: texts are easier to understand without such discontinuities, and discontinuities often point to a lack of text planning during writing (Sanders and Schilperoord, 2005).

The use of text analysis in document design is particularly promising because it not only appears valuable in the study of 'classical' text structure, but it is also a useful basis to investigate the matching of text structure, content, and layout, including visual images (Delin and Bateman, 2002). This type of work shows the way to the text analysis of the 21st century: that of multimodal documents.

Introduction

The *text formatting* problem, to be solved by software residing on a computer, is to take a sequence of words stored in an input file and arrange them in the same order on as many pages as are needed, subject to the user's commands and his choices on a variety of constraints and options. The pages can be printed on paper at any time, and usually the user is able to see on the computer's screen approximately how the pages will appear when printed. The approximation is usually accurate to the resolution of the computer's screen.

The results the user gets depend on the commands he gives and on the value of the choice he makes for each constraint or option. These commands are given and choices are made by directly or indirectly (see the later discussion on direct manipulation) inserting additional characters, often called *markup*, at appropriate points in the input file. Later in the article, the commands are summarized and a full list of constraints and options is given. In the mean time, the constraints and options are collectively referred to as 'choices.' Telling a formatter to apply a particular option is called *turning the option on* and telling the formatter not to apply a particular option is called *turning the option off*.

For concreteness, the text that you are now reading was formatted in lines that are 3.154 inches (80.1 millimeters) wide, in the Sabon family of typefaces at the 10 point size on lines spaced at 12 points. The text is strictly left to right and is left- and right-justified with hyphenation turned on. The commands issued were mainly for introducing the title, introducing the author's name, introducing sections, introducing

processes in reading: Perception and comprehension. Hillsdale, NJ: Erlbaum. 265–303.

Introduction

The *text formatting* problem, to be solved by software residing on a computer, is to take a sequence of words stored in an input file and arrange them in the same order on as many pages as are needed, subject to the user's commands and his choices on a variety of constraints and options. The pages can be printed on paper at any time, and usually the user is able to see on the computer's screen approximately how the pages will appear when printed. The approximation is usually accurate to the resolution of the computer's screen.

The results the user gets depend on the commands he gives and on the value of the choice he makes for each constraint or option. These commands are given and choices are made by directly or indirectly (see the later discussion on direct manipulation) inserting additional characters, often called *markup*, at appropriate points in the input file. Later in the article, the commands are summarized and a full list of constraints and options is given. In the mean time, the constraints and options are collectively referred to as 'choices.' Telling a formatter to apply a particular option is called *turning the option on* and telling the formatter not to apply a particular option is called *turning the option off*.

For concreteness, the text that you are now reading was formatted in lines that are 3.154 inches (80.1 millimeters) wide, in the Sabon family of typefaces at the 10 point size on lines spaced at 12 points. The text is strictly left to right and is left- and right-justified with hyphenation turned on. The commands issued were mainly for introducing the title, introducing the author's name, introducing sections, introducing

paragraphs, giving numbered and labeled lists, specifying footnotes, and including figures.

Each formatter worth its salt allows the user to give commands and to set the value of all choices. Some do not allow making some of these choices, e.g., one very popular formatter in its academic, not professional, version does not allow installing automatic hyphenation.

The formatters that are considered in this article are MS Word (Microsoft, 2000), FrameMaker (Adobe Systems Incorporated, 2000), TEX (Knuth, 1988) with LATEX (Lamport, 1994), ditroff (Ossana, 1976; Kernighan, 1982), and the Mozilla browser (Mozilla, 2004). (LATEX is TEX extended by macrodefined commands that implement a collection of aesthetic designs for a variety of document types used by computer scientists.) These are both representative and available, and are widespread in some sense of the word. The online version of this article shows the text of this article formatted by each of these formatters, both with and without hyphenation if possible, in a two-column format that resembles as much as conveniently possible the hard copy you are looking at right now. (The IEEE two-column conference proceedings format was readily available for all the listed formatters except Mozilla. The author is not enough of an expert in all of these formatters to be able to match the encyclopedia's format exactly; so this close match is used instead.)

In this article, each formatter is classified by the choices it makes for the user and what it allows the user to choose.

This article discusses each choice, i.e., constraint and option, by briefly describing both the algorithmic issues involved and the effect each choice has on the appearance of a formatted document. Many of these choices interact with each other.

The plan for this article is:

1. to define some terms;
2. to describe properties of the text to be formatted;
3. to describe the basic formatting algorithms in terms of their effects; and
4. to present each constraint and option in terms of its effect on the formatting algorithm and in terms of its effect on the final appearance of a document.

The focus of this article is strictly on the formatting issues. For details of computer typefaces and typography, *see* **Digital Fonts and Typography**.

Terms

Document The text being formatted is called the *document*.

Input, Output, and Output Lines This article distinguishes between *input* and *output*. The input is a sequence of characters some of which are space, tab, newline, and endfile. The output is a collection of characters each printed at a particular position on a page. A collection of characters with the same horizontal position forms an *output line*. If we consider the characters of one output line listed in order of their vertical positions, then we can talk about the sequence of characters in the output line.

Character Bounding Box, Glyph, Side Bearings, Width, Boundary, and Adjacency See Figure 1 for an output line consisting of the two nonsense words 'Hmg Hmg' printed at a very large size. In this figure, various axes, distances, and properties of the characters are identified, and these are the subject of the following discussion.

In a modern printer that accepts PostScript as its page description language, each character has a *bounding box*, an imaginary rectangle that circumscribes the shape of the character, known also as the character's *glyph*. The bounding box is shown explicitly for only the first 'g'. If the character is not to connect with its neighbors, as is the case with nonscript versions of Latin letters, then to the left and to the right of the bounding box are some regions in which nothing is printed. The region to the left of the bounding box is called the *left side bearing* and the region to the right of the bounding

Figure 1 Nonconnected Latin characters with axes.

box is called the *right side bearing*. In this article, the left edge of the left side bearing is called the *left boundary* of the character, and the right edge of the right side bearing is called the *right boundary* of the character. The distance from the left boundary to the right boundary of a character is the character's *width*. Characters within one word, such as each 'Hmg' in Figure 1, are normally printed with their side boundaries touching each other. Two characters with boundaries touching each other are called *adjacent*.

All the characters on one output line are printed on a single *base line*. The intersection of a character's left boundary and the base line is called the character's *origin*. Thus, for a pair of adjacent characters, the origin of the right-hand character coincides with the left-hand character's right boundary.

Figure 2 shows two Arabic characters that connect with each other. For each, the side bearing on the connecting side is zero. As a result, if the connecting pieces of two adjacent connecting characters meet their boundaries over the same range of y values, then when the character's boundaries touch, the characters end up connecting.

Blank A *blank* character in an input line is a space, a tab, a newline, or an endfile character.

Word and Chunk A *word* in either kind of line is a sequence of adjacent nonblank characters. These characters are typically mostly letters and may occasionally include, especially at the end, a punctuation character. However, from the point of view of the formatting process, the nature of the characters is somewhat irrelevant. Of course, the notion of hyphenation is relevant only for words consisting only of letters and possibly one punctuation symbol at the end.

In input to a formatter, words are separated by and delimited by blank characters.

When hyphenation is turned on in a formatting, then, occasionally, a word will be broken into two pieces. Appended to the first piece will be a hyphen character.

Figure 2 Connected Arabic characters with axes.

The word *chunk* is used in this article to refer to a unit of formatting. Each nonhyphenated word, each first piece of a hyphenated word together with the appended hyphen, and each second piece of a hyphenated word is called a *chunk*.

Space Character Generally, the characters inside a chunk are printed adjacent to each other. When two consecutive chunks are printed on the same output line, the last character of the first chunk is not adjacent to the first character of the second. In Figure 1, the first 'g' at the end of the first 'Hmg' is not adjacent to the second 'H' at the beginning of the second 'Hmg'. The region of the output line between two consecutive chunks, in which no character is printed, is called the *space* between the chunks. The minimum size of a space between chunks is usually about the same as that of a narrow character such as 'i'. This minimum spacing between chunks is often called *the space character* even though nothing is really printed.

More about Output Line An output line of a formatted document then consists of consecutive chunks in a sequence with some nonprinted space in between them. At most the last chunk of a line is the first piece of a hyphenated word together with its appended hyphen. Generally, almost all lines of a document are the same length; the first and last lines of any paragraph may be shorter than this common length.

Output Page An *output page* of a formatted document consists of a sequence of lines. Generally, the number of lines in almost all pages in a document are the same; the first and last pages of a chapter may have fewer lines than others.

Justification and Raggedness When all the lines of a page have text right up to a margin, either left or right, then the lines are said to be *justified* to that margin. Conversely, if all the lines of a page do not meet a margin, either left or right, leaving some space between the chunk closest to the margin and the margin, then the lines are said to be *ragged* at that margin. In most documents, e.g., this article, lines are left- and right-justified. In some Latin-alphabet documents, lines are left-justified and right-ragged. Very rarely, mostly only in poetry, one finds portions of Latin-alphabet documents whose lines are left-ragged and right-justified. One does find portions of documents in which all lines are centered, effectively making the lines left- and right-ragged.

Formatting To use the vocabulary just established, *formatting* can be described as the process of arranging the words of an input document into chunks laid

out in output lines on output pages according to commands, constraints, and options provided and set by the user.

Text Characteristics

The text of a document to be formatted can be in a mixture of human languages, each with its own character set. Some languages, e.g., English, French, German, and Russian, are written from left to right with lines flowing from top to bottom. These are called the *LR* languages. Other languages, e.g., Arabic, Hebrew, and Persian, are written from right to left with lines flowing from top to bottom. These are called the *RL* languages. Still other languages, e.g., Chinese, Japanese, and Korean, are written from top to bottom with lines flowing from right to left. These are called the *TB* languages.

To a formatting algorithm, the specific languages of a document do not matter beyond the direction in which its text is written. Two different languages that are written in the same direction are equivalent from the formatter's point of view, even if they use different alphabets. The different alphabets can be regarded as no more than different typefaces. Therefore, this article talks only about the three directions of text, LR, RL, and TB, and not the actual languages in which the text is written. Of course, the rules for hyphenation do depend on the language of the text.

A document, or more properly, a section of a document, has a *document direction*. For example, a book in English about the Arabic Koran is a left-to-right (LR) document, even though it contains quotations in Arabic. A book in Hebrew about Shakespeare is a right-to-left (RL) document, even though it contains quotations in English. A book in Chinese about the Hebrew Bible is a top-to-bottom (TB) document, even though it contains quotations in Hebrew. The document direction establishes the general flow of lines. It establishes also the side on which various formatting commands are obeyed. For example, if paragraphing means indenting the first line of the paragraph, then in a RL document, that indentation is from the right margin.

Document direction can be changed in the interior of a document. Therefore, there is the notion of the *current document direction at any point*. If a quotation in a language of a different direction is lengthy and is stretching over several paragraphs, it might be convenient to change the document direction for the duration of the quotation, so that the quotation's paragraphs are indented from its correct side.

To be direction independent, this article uses the terms *start* and *end* to designate the sides of a page in which a line starts and ends. Thus, in an LR document the right margin is called 'the end margin,' whereas in an RL document the right margin is called 'the start margin.'

Text in which each language is printed in its own direction is said to be in *visual order*. Although different languages may be written in different directions, all languages are spoken in the same direction, namely forward. Therefore, for ease in input, the convention is that the characters of a mixed-language document are stored in an input file in the order that they are spoken when a knowledgeable reader is reading aloud the visually ordered text of the mixed-language document; this reader knows the rules about reading visually ordered multidirectional text. This stored order of characters is called *time order*. That text is stored in time order means that the characters may be keyed in in the order that they are spoken. It is the job of the formatter to arrange the output so that the text is written in visual order, so that the time ordering is recreated when a person who knows the rules about reading multidirectional text reads the visually ordered output.

Here is an example of a line containing left-to-right English and right-to-left Arabic and Hebrew text displayed in the visual order that is used in the Middle East:

Dana said, "שלום דניאל ، دانيال سلام" to Daniel.

Because this line is in a left-to-right document (this article), it is read in an overall left-to-right direction. Any embedded right-to-left text is read in its left-to-right turn, but from right to left. Thus, this line is read:

1. Dana said, "[*from left to right*]
2. שלום דניאל ، دانيال سلام [*from right to left*] (*salaam danyal, shalom danyel*)
3. " to Daniel. [*from left to right*]

Here is the same line in time order, giving each character in the order it is pronounced when a knowledgeable reader reads aloud the visually ordered line above:

Dana said, "לאינד סולש ، لايناد مالس" to Daniel.

Even if you cannot read the Arabic and Hebrew phrases in between the pairs of English quotation marks, you should be able to see that in the two lines, the directions of their characters are reversed. Note that in the visually ordered line some of the Arabic characters connect to each other, but none of

the Hebrew and Latin characters connect to any other.

Basic Formatting Algorithms

A formatting algorithm is described as occurring over time. Thus, there is always the notion of *current, past*, and *future*. There is the *currently read and processed character or chunk of the input*. There is a *current output line being constructed*; there are the *characters or chunks already inserted into the line*.

There is a *current page being constructed*; there are the *lines already inserted into the page*. The article talks about *output lines being built character-by-character or chunk-by-chunk from left to right* and about *output pages being built line-by-line from top to bottom*. If part of the text flows in a different direction, then the formatter is regarded as having to reorder the characters of this part before inserting them into the lines and the pages, so that when a user reads the constructed lines and pages, the text appears to flow in the proper direction.

The reality is that a page to be printed is described in a page description language such as PostScript (Adobe Systems Incorporated, 1992) or PDF (Adobe Systems Incorporated, 2001). A page to be printed is not necessarily built in this strict left-to-right, top-to-bottom order. However, the results are always equivalent to having been built in this strict order.

A formatting algorithm is classified by the number of *passes* it makes over the input. If an algorithm reads the input only once, it is called a *one-pass* algorithm, etc. An algorithm must have at least two passes if information it needs to format the beginning of of the input cannot be known until it has seen the end of the input. Sometimes, a formatter, e.g., TEX, can simulate an additional pass for a specific purpose by saving in an external file the information that is needed earlier than it is found. This external file is read on the next run of the formatter on the same input.

Describing a formatter requires describing both formatting algorithms and options. Describing each requires understanding the other. To break this vicious cycle, this article describes first vanilla formatting that depends on standard settings of options. Then, an option can be described in detail by describing the effects the option has on vanilla formatting. In the description of vanilla formatting, there are references to some ideas that are described more completely later.

Vanilla formatting deals with ordinary word-by-word unidirectional text that occurs in the interiors of paragraphs. Most any formatter provides ways to achieve special effects, e.g., chapter and section headers; paragraph breaks; centering; indentation; bulleted, enumerated, or labeled lists; footnotes; formulae; tables; etc. Each such feature involves local changes that are quite straightforward to achieve. However, even in these features there are snippets of ordinary text that must be handled by the general formatting algorithms described below.

The simplest formatting algorithm operates on a line-by-line basis. That is, each output line is filled with as many words from the input as is possible given the current typeface size and an adequate minimum spacing between each pair of words. There is a last full word that fits in the output line, and there is its successor word in the input that does not fit in its entirety in the output line. If hyphenation is turned on, this successor word is examined to see if it can be broken into two pieces according to the currently invoked hyphenation rules, such that the first piece together with an appended hyphen fit into the output line being built. If so, the chunk formed by that first piece plus an appended hyphen is added to the output line being built. If there is no suitable way to divide that next word, the output line is ended with the last inserted full word.

Now, if the formatter does not end-justify output lines, the output line is finished, leaving the output with a ragged end margin. If the formatter does end-justify output lines, then the chunks in the output line being built are spread apart with additional space as much as is necessary so that the distance between the start of the first chunk and the end of the last chunk is the line length. Generally, the spreading is done so that the sizes of the spaces between all pairs of chunks are the same.

Line-by-line formatting is used by ditroff, and it appears, because of the variability of spacing from one line to the next, to be that used by MS Word, FrameMaker, and the Mozilla browser. (The manuals or help systems do not discuss this issue, and the author does not have access to any of the source code. In the cases of ditroff and TEX, the author has access to the proprietary and open source code, respectively. Thus, he is able to be certain about the behavior of the algorithms of ditroff and TEX. This observation applies to all claims of appearance of the behavior of an algorithm.)

You may be surprised to learn that HTML (WC3, 1999), the language of the input to Web browsers, such as Mozilla, allows specification of end-justification on a paragraph basis. In the '<p>' markup defining the beginning of a paragraph, if one says '<p ALIGN = "JUSTIFY">', the paragraph at hand is end-justified when displayed by a browser. Mozilla does a reasonable job of justification on a line-by-line basis. However, Netscape forces end-justification for some, but not all, last lines of paragraphs, creating

very large gaps between words in last lines that are less than about 7/8 full.

An enhancement to this simple and any formatting algorithm is to make the space following punctuation a bit longer than that after no punctuation. An enhancement of this enhancement is to make the space following a sentence-ending symbol (e.g., a period) a bit longer than that following a clause-ending symbol (e.g., a semicolon), which in turn, is a bit longer than that following a phrase-ending symbol (e.g., a comma). TEX uses these enhancements and FrameMaker appears to use these enhancements.

The main problem with this simple formatting algorithm is the large variation in the interword spacing from line to line or in the distance from the end chunk to the end margin. When there is end-justification, the interword spacing on each line is computed independently of the interword spacing on all other lines. Thus, there can be large variations between the interword spacing on adjacent lines. Some believe that this variation is ugly. Some find it annoying, and some find it tiring to read, as the mind cannot get used to any one spacing for very long. When there is no end-justification, the space between chunks is uniformly equal to that of the space character. However, there can be large variations in the space after the end word on each line, giving rise to a very ragged end edge of the text.

Turning hyphenation off exacerbates these variations because on average, each line has fewer words and more space to distribute between the words or after the end word. This exacerbation is a problem with formatters with no automatic hyphenation, such as Mozilla and some versions of MS Word. Automatic hyphenation is not even available in some versions of MS Word 2000. (An attempt to turn on automatic hyphenation in the educational version of Word 2000 that this author has fails. Word asks that the user install hyphenation. When the Educational Office 2000 CD is inserted, the user is told that the Professional version must be inserted.) Moreover, based on the appearance of many Word-typeset documents, it appears that many users do not bother to turn automatic hyphenation on.

When the line length is short compared to the typeface size, such as in newspaper columns, the variation in interchunk spacing is even more pronounced. When there is end-justification, the result is what is called *rivers of white space*, with large gaps of space between very few words on a line. Sometimes, only one word can be fit on a line, forcing either a ragged edge in the middle of start- and end-justified text or space between the characters of the one word.

Perhaps the best variation of the basic formatting algorithm is to format a whole collection of output lines, e.g., those of one paragraph, together. This variation is the approach of TEX and thus of LATEX. TEX's algorithm uses dynamic programming to find the choice of line breaks that yields the least variation in spaces between the chunks in the presence of double justification and the least raggedness of the end margin when end-justification is turned off (Knuth and Plass, 1981). Thus, a line may not be as full as it can be. If under the simple line-by-line algorithm, one line has significantly larger spacing between the words than the previous line, it is possible that moving the last word of the first of these lines to the second line will result in interchunk spacing that is more uniform over the two lines. For example, compare the spacing in the two lines:

```
11    22    33    44    55
66666                 77777
```

with that in the two lines of the same length:

```
11       22       33       44
55       66666       77777
```

Even though the '55' fits into the first line, spacing is more uniform in the two lines when the '55' is put into the second line. In this manner, TEX's algorithm tries to find the best assignment of chunks to lines of a paragraph, which results in the most uniform sized spaces in the lines of the paragraph. The result is that TEX's interchunk spacing is the most uniform and pleasing of all formatters.

Formatter Operation

There are two basic flavors of formatters:

1. *WYSIWYG (what you see is what you get), direct manipulation* and
2. *compiled from mark up*.

MS Word and FrameMaker are examples of the former. TEX, LATEX, ditroff, and the Mozilla browser are examples of the latter.

A WYSIWYG, direct-manipulation formatter presents to the user a window containing an approximation of part of one page of the output of the document. The user operates a pointer (e.g., a mouse) to indicate directly where in the page a command is to be obeyed. When a user types characters to be inserted at the pointed-to spot, the characters seem to be inserted one by one directly into a growing line. The result is that when characters are inserted into a new document, the document appears to grow on the screen the same way a typewritten document would grow on paper if the same characters were typed. Of course, the analogy with the typewriter falters when the user

backspaces to remove characters or when characters are inserted in the midst of an already full page.

At any time, what the user sees on the screen is a close approximation of what would show up on paper if the document were printed at that time. The approximation is supposed to be as good as the screen resolution allows. The user makes changes to the document by what appears to be directly manipulating the document at the places of the changes.

A formatter that compiles from markup translates an input file into page description language commands that print the formatted pages. The input file contains the time-ordered text of the document with commands inserted at the proper places. Each command is applied at the spot it appears to the text that immediately precedes and follows it. These commands are often called *markup*. Figure 3 shows parts of the inputs of this article to the ditroff, LaTeX, and Mozilla formatters. The part shown for each is of the same part of the document, the first paragraph of this section. You see the markup for beginning a section, for beginning a paragraph, for a numbered list, for italicizing text, and, in some cases, for referencing macros to typeset the words 'TeX' and 'LaTeX' in their fancy ways.

Some of the compiled-from-markup formatters have WYSIWYG, direct-manipulation front ends or WYSIWYG previewers that allow at least previewing what will be printed if not direct manipulation.

However, the user must remember that what is manipulated is the marked-up time-ordered input file.

The reality for a WYSIWYG formatter is that the internal representation has the text with markup, this markup being inserted into the internal representation as a result of the user's direct manipulation on the screen image of the document. In other words, if a user indicates that some selected sequence of characters should be italicized, then internally, there is some indication in the internal representation of the selected characters that says they are now italicized; that indication is effectively markup.

The algorithms given in this article are used in each kind of formatter, albeit in a different way. In a compiled-from-markup formatter, these algorithms are used as part of the translation process exactly as described. In a WYSIWYG, direct-manipulation formatter, these algorithms appear to be applied by the formatter on an incremental basis in order to update the appearance of what the user sees on the screen to what it should be after each change to the document. Optimizations are used to try to compute rapidly the change to what is visible to the user without having to format the whole document after each tiny change. The changes appear to be propagated to the rest of the document during idle periods, when the user's input has slowed down a bit.

Constraints and Options

A *constraint* is a physical attribute of formatting that has continuous scale of values. An *option* is feature which may or may not be turned on at any given point of any given formatting. Sometimes a collection of options may be mutually exclusive; only one of them can be turned on at any given time.

Constraints

The main constraints of formatting are the size of the typeface, the spacing of the lines, and the dimensions of the printing area.

The size of a typeface is measured in points, each of which is approximately 1/72 inch or .352778 millimeter. The concept comes from the days in which typesetting was done by assembling *metal pieces of type*, one for each character to be printed, into rows, one for each line to be printed. On the face of each such piece was embossed one reversed character. When ink was spread on the faces of the assembled metal pieces and paper was pressed to the faces, the characters appeared on the paper oriented correctly. The size of a typeface was the common height of these pieces of metal type on which characters were embossed. This height would be a bit bigger than the distance from the bottom of the lowest descender, e.g., the bottom of the 'q', to the top of the highest ascender, e.g., the top of any uppercase letter. This distance is called called *the point size of the typeface*. The most common point size used in books and newspapers is 10. Generally, one does not find smaller than 6 point type, because humans have problems reading text even as small as that. Display type and headlines may be up in the 36 or 72 point range or even higher.

Also the spacing of the lines of the text is measured in points. It is measured by the distance between the baselines of two consecutive lines of the text. Normally, the line spacing is 120% of the current point size; this spacing yields a comfortable single spacing. Thus, for 10 point type, the usual spacing is 12 points. Smaller than that, e.g., at 110% of the point size, looks rather tight. If the spacing is equal to the point size, then a descender on one line may come very close to touching an ascender on the next line. Spacing that is 180% of the point size is called 1.5 spacing and spacing that is 240% of the point size is called double spacing.

The spacing between lines used to be implemented by strips of lead 1 or 2 points wide placed between the assembled rows of pieces of metal. Hence, the difference between the line spacing and the typeface point size is called *leading*. Thus, 10 point type with 12 point spacing has leading of 2 points.

The dimensions of the printing area is usually measured in picas, each of which is 12 points, about 1/6 inch or 4.2333 millimeters. When one is printing single-spaced 10 point text on letter-sized paper, a typical line length is 39 picas or 6.5 inches. At 12 point spacing, a typical number of lines is 51, covering 51 picas or 8.5 inches. On A4 paper, a typical line length might be 38 picas or about 16 centimeters, and a typical number of lines might be 52, covering 52 picas or about 22 centimeters.

Clearly, the larger the printing area, the smaller the line spacing and the point size, the more text can be printed per page. Moreover, the longer the line width and the smaller the point size, the more uniform is the spacing between the chunks on a line, because more chunks can be put into a line. With very short line lengths or large point sizes, one may be put in a situation in which only one or two chunks can be put on a line, and the spacing between chunks in lines varies radically.

The longer the line width and the smaller the text size, the less necessary is hyphenation to reduce the variability of the spaces between chunks on a line.

Options

The main options concern directionality; hyphenation; justification; pagination; and figure, table, and footnote placement.

Directionality The typical document is unidirectional. That is, all of its text is written in one direction. For example, if a document is an English document, then all of its text is written from left to right. That is, the start of an output line is on the left side of a column of lines and the end of a line is on the right side of the same column of lines. In the vanilla formatting algorithm, filling an output line starts at the left margin, and it ends when adding another word would leave its right end sticking out past the right margin. End-justification causes the last chunk on the right end of an output line to end at precisely the right margin of the line.

Conversely, if a document is an Arabic or Hebrew document, then nearly all of its text is written from right to left. (In Arabic and Hebrew, numerals are written from left to right, i.e., a phone number is written with the first dialed digit on the left side. Users of Arabic and Hebrew typewriters have learned to enter numerals backward.) That is, the start of an output line is on the right side of a column of lines and the end of a line is on the left side of the same column of lines. If the vanilla formatting algorithm is applied in the right-to-left direction, filling an output line begins at the right margin, and it ends when adding another word would leave its left end sticking out past the left margin. End-justification causes the last chunk on the left end of an output line to end at precisely the left margin of the line.

There is also the possibility of top-to-bottom writing of text, e.g., for Chinese. In traditional Chinese printing, a line is written from the top of the page to the bottom, with lines laid out from right to left. The details of the vanilla formatting algorithm can easily be adjusted to deal with such top-to-bottom text. Indeed, as is shown in Figure 4 with two layouts of a famous two-line poem by Li Bai, a top-to-bottom layout is identical to a left-to-right layout with the characters rotated 90 degrees counterclockwise.

Alternatively, a document may be multidirectional. The most common multidirectional document is bidirectional, e.g., for a mixture, say, of English with Arabic and Hebrew. Indeed, because of the presence of left-to-right numerals, a plain Arabic or Hebrew document can be considered bidirectional. When formatting a bidirectional document, the assumption is that the entire input is stored in *time order.*

The basic bidirectional formatting algorithm assumes this time-ordered input and needs to know at any time the current document direction and the current text direction. The current document direction is as described in the subsection titled 'Text Characteristics.'

At any time, the current text direction is the direction of the language of the currently considered character. A Latin character is generally left-to-right (a user can declare otherwise for special effects, e.g., to mimic Da Vinci's writing) and an Arabic or Hebrew character is generally right-to-left. A seemingly neutral character, e.g., a period, must be regarded as having the direction of its language; thus, there is a left-to-right period and a right-to-left period.

牀前明月光，疑是地上霜。
舉頭望明月，低頭思故鄉。

牀前明月光，疑是地上霜。
舉頭望明月，低頭思故鄉。

Figure 4 Left-to-right and top-to-bottom layouts of same text.

The basic bidirectional algorithm (Buchman *et al.*, 1985; Knuth and MacKay, 1987; Srouji and Berry, 1992; Berry, 1999; Habusha and Berry, 1990) has a standard unidirectional formatting algorithm first break the time-ordered input into lines, taking into account point size, line length, hyphenation, and justification, as if all the text in the document were left to right. Then on a line-by-line basis, the text of each output line is reordered:

```
for each output line in the document do
  if the current document direction is LR then
    reverse each contiguous sequence of RL
      characters in the line
  else (the current document direction is RL)
    reverse the whole line;
    reverse each contiguous sequence of LR
      characters in the line
  end if
end do
```

You should verify that applying this algorithm to the time-ordered Arabic, English, and Hebrew line:

Dana said, "سلام دانيال ، שלום דניאל" to Daniel.

yields the visually ordered line:

Dana said, "שלום דניאל ، سلام دانيال" to Daniel.

Less common among the multidirectional documents is the tridirectional document. There is an

algorithm assuming all input in time order that lets a unidirectional formatter format the time-ordered input file, and then, it reorganizes the characters of the output so that left-to-right text is written from left to right, right-to-left text is written from right to left, and top-to-bottom text is written from top to bottom (Becker and Berry, 1990). It deals with the two horizontal directions as does the bidirectional formatting algorithm. There is an algorithm for doing the reorganization of the top- to-bottom text after bidirectional formatting is done. This algorithm takes advantage of the fact that all characters in Chinese, Japanese, and Korean have bounding boxes that are squares of the same size; thus, any character fits in the bounding box of another. Figure 5 shows a visually ordered tridirectional English, Hebrew, Japanese, and Chinese document; the English text is printed from left to right from the left margin on one line; the Hebrew text is printed from right to left from the right margin on the next line; the Katakana Japanese text is printed from left to right from the left margin on the next line; and finally the Hiragana Japanese text and the Chinese text is printed from top to bottom at the right margin. Figure 6 shows a stylized time-ordered input for the output of Figure 5; each printed character is shown in its output form, and among this input, there is HTML-like markup defining the language of the text and the applicable document directions. Space constraints do not permit giving the details of the algorithm here.

Justification The most common choice for justification is whether or not there is end-justification. Some formatters offer also the option of end-justification without start-justification. For example, in a left-to-right document, this justification regime is right-justification and ragged-left. Each line is filled with as many chunks as possible and then all the text is shifted to the right so that the last chunk is flush with the right margin. In terms of the variability of the spacing between words and of the space from the start margin to the start chunk of a line, this justification regime, called *start-ragged*, is equivalent to end-ragged.

Hyphenation There are two basic choices concerning hyphenation, turning it on or off. If hyphenation is on, the formatter usually uses a hyphenation algorithm that implements basic English hyphenation rules combined with a dictionary, perhaps the same one that is used for spelling checking. Some formatters offer the possibility of overriding the automatic hyphenation decisions with explicit indications of possible hyphenation points in a word, including that there are none. This indication may be directly in the words in the input file or in a separate file providing the user's hyphenation dictionary. When a formatter offers the feature of overriding automatic hyphenation rules, the feature can be used to cause hyphenation according to the rules of a language other than English. Either a prepass goes through the document inserting explicit hyphenation points in every word according to the other language's hyphenation rules, or the prepass builds a user's dictionary for the words in the document, again according to the other language's hyphenation rules. TEX has a table-driven hyphenation algorithm that is provided with a default table for English. Tables describing the rules for another language can be installed in any formatting run.

Most formatters offer the choice of turning hyphenation on or off. As mentioned, some versions of MS Word 2000 have it, but some do not. In practice, MS Word documents are rarely hyphenated. TEX, ditroff, and FrameMaker have hyphenation, and it is easy to turn on in each. The Mozilla browser has no automatic hyphenation.

Pagination The pagination problem is that of determining when the current page is filled with lines. In the absence of stylistic considerations, the problem is almost identical to that of determining when a line is

filled with words. Basically, if the next line would end up below the bottom margin on a page, the current page is ended; an optional page footer, including an optional page number is issued; a new page is begun; an optional page header, including an optional page number is issued, and then the postponed line is inserted as the first line on the new page. Some complexity comes when for stylistic reasons, we do not want to create *orphan* or *widow* lines. A orphan line is a section header or first line of a paragraph as the last line on a page. An widow line is a last line of a paragraph as the first line of a page. Neither a orphan nor an widow looks good sitting there all by itself.

It is fairly easy to avoid orphan lines. The formatter can examine any section header or any first line of a paragraph and determine if it would be the last line on a page, that is, there is not enough room to print at least two more lines after the section header or at least one more line after the first line of a paragraph. (At least two more lines are needed after a section header to prevent the first line of the section's first paragraph from being an orphan in its own right.) If there is not enough additional space on the page, the section header or first line of a paragraph goes on the next page.

Avoiding widows is more complex, as it requires having determined one line before the last line of a paragraph, that the next line, i.e., the last line of the paragraph, will end up on the next page. If this determination can be made, then a solution is to terminate the page one line sooner and to put both the next to the last line and the last line of the paragraph on the next page. This determination requires either looking ahead or that page breaking be done in a two-pass algorithm. For many formatters, which operate strictly with one formatting pass, the only solution is for the user to notice the widow in one formatting of the document and to then to issue in the next formatting of the document an explicit page break instruction at the right point. The user thus implements a two-pass algorithm manually; that is, after the user's observing the widow and fixing the input, the next run of the formatter is effectively the second pass. When a formatter has a look-ahead or a two-pass algorithm, there is a complexity that shows up only when footnotes, figures, and tables have to be placed automatically, as is discussed in the next subsection.

This article is printed in double-column pages. To a formatting algorithm, each column is a page, albeit a narrow one. The formatter does have to be a bit careful not to give each column its own page number and other header and footer items. Also, it is considered good style to make sure that the lengths of all columns sharing a physical page are the same length.

Placement of Figures, Tables, and Footnotes The general problem is that each figure, table, or footnote may be printed in a place different from that in which it is referenced. A figure or table should appear in its entirety no earlier than the beginning of the page in which it is first referenced. The preference is that a footnote should appear, in its entirety, at the bottom of the page on which it is referenced. However, that may not be possible; there may not be enough room between the footnote reference and the bottom of the page for the entire footnote. In this case, the footnote has to be split over a page boundary. A figure must not be split at a page boundary. A footnote may be split at a page boundary. Tables are a special case; each may be split or not split, depending on the user's taste. Many prefer not to split a table that has vertical lines, and many consider a table with no vertical lines to be splittable. Thus, a figure or nonsplittable table must be printed in its entirety within the margins on one page. Each figure, table, or footnote is what is called a *floater*; that is, it is floated to where it can be printed according to the constraints described below. A figure or nonsplittable table is indivisible and must be printed in its entirety on one page. A footnote or a splittable table may be split at page boundaries.

This article has figures but no tables. The definitions of each of these figures were supplied just after their first references. However, you see them elsewhere. Therefore, these items were floated.

It is assumed that the full figure, table, or footnote is input just after the first reference to it. This way, the formatter is able to read the figure, table, or footnote immediately after encountering the first reference to it. The formatter thus knows how big the footnote, table, or footnote is; and it knows whether the table is splittable. It is assumed also that any captions are part of the figure or table.

There are two basic algorithms for placement of figures, tables, and footnotes:

1. *one-pass greedy* and
2. *multipass, optimizing in some sense*.

In a one-pass, greedy algorithm, after seeing a footnote reference and its footnote, the formatter first reads enough of the text after the footnote to fill out the output line containing the reference. Then, the formatter notes whether there is sufficient room on the current page for the entire footnote. If not, the formatter splits the footnote into two pieces, the part that fits on the current page and the rest. Then it prints the first piece, ends the current page, and arranges for the rest to be printed on the next page as the first footnote. Note that there may be recursion

here as the rest may have to be split over the next page and the pages after that.

In a one-pass greedy algorithm, after seeing a figure reference and its figure, the formatter first reads enough of the text after the figure to fill out the output line containing the reference. Then, the formatter notes whether there is sufficient room on the current page for the entire figure. If so, the formatter prints the figure on the current page and continues normal formatting after the bottom of the figure. If not, the formatter arranges to print the figure on the top of the next page and to move, or to *bubble up*, the text that follows the figure to fill in the space at the bottom of the page that was not big enough for the figure. If the figure is simply too large for any page, then the user must arrange to shrink the picture to fit.

A nonsplittable table is treated as a figure.

The steps of a one-pass greedy algorithm are illustrated by some of the parts of Figure 7 that is used to describe several different formatter's algorithms. Each part, (a) through (e), shows a page on top and the next page in the bottom. An upside-down 'T' represents a reference to the figure or table that follows it. Each of parts (a) and (b) represents a situation in which a figure or nonsplittable table fits on the current page. Parts (c), (d), and (e) represent three steps in the treatment of a one-pass greedy algorithm on a figure that is too big to fit on the current page. Part (c) shows the algorithm discovering that the figure or table does not fit on the current page. Part (d) shows the algorithm floating the figure to the top of the next page. Finally, Part (e) shows the algorithm bubbling the text that logically follows the figure or table to the space on the first page vacated by the figure or table that was floated.

In a one-pass greedy algorithm, after seeing a reference to a splittable table and the table itself, the formatter first reads enough of the text after the table to fill out the output line containing the reference. Then, the formatter notes whether there is sufficient room on the current page for the entire table. If so, the formatter prints the table on the current page and continues normal formatting after the bottom of the table. If not, the formatter prints what it can of the table on the current page, ends the current page, and prints the rest of the table on the top of the next page.

Note that the formatter may have to deal with several floaters at once. Doing so is no real problem, as floaters or their pieces can be merged. There is a slight complexity introduced by having to deal with orphan lines in the presence of floats. It may be necessary to avoid a orphan before a figure, table, or footnote appearing at the bottom of a page.

In a multipass, optimized-in-some-sense algorithm, the algorithm uses the first pass to note all the floaters as well as potential orphans and widows and uses some dynamic programming technique to try to place a floater no earlier than the top of the of the output page in which it is referenced and to balance page lengths while avoiding orphans and widows. Sometimes there can be no optimal solution meeting all the constraints, and a figure or table may float to a page before it is referenced or blank lines not in the input are inserted into the output.

Ditroff uses a one-pass greedy algorithm. TEX and LATEX use a multipass algorithm. Because Mozilla has an unbounded page length, it does not have to float any figure or table. A figure or table is placed where it occurs. Footnotes have to be manually placed either where they are referenced as parenthetical remarks, or as end notes, deferred to the end of the page at hand. Word and FrameMaker appear to use a one-pass algorithm, but there is more discussed below, arising from their WYSIWYG, direct-manipulation nature.

The disadvantage of a greedy algorithm is that it sometimes ends up having to put a floater long after its reference because of an overbooking of floaters all referenced very near to each other. Also, sometimes manual intervention is required to deal with widows and to achieve better placement of floaters by putting some floaters before they are referenced. With a multipass algorithm, these manual interventions should not be necessary.

However, the disadvantage of the multipass algorithm is that a figure or table may end up on a page before it is referenced. Also the floater placement and page breaks are very unstable. It occasionally happens that inserting new text **after** a figure causes that figure to move up, changing floater placement completely. If one has been working hard to get floaters placed in a pleasing manner, and has done so in all previous pages, one can find a change on the current page causing a reorganization of previous pages.

A one-pass greedy algorithm is very stable in the sense that no change can affect the output of the text lying before the change. Thus, while manual intervention is required to achieve optimal placement and widow avoidance, one is assured that once he has achieved the desired formatting of pages up to the current one, no change to what follows can affect this formatting. The user can proceed safely through the document page-by-page, getting each page right before going on to the next page with assurances of the immutability of what has already been gotten right.

Particularly messy is the placement in multiple-column text of figures and tables that are wider than

Figure 7 Treatment of figures and tables.

the column width. The placement of a figure or table in one column can have a true side-effect on a neighboring column whose text must flow around the too-large figure or table that extends into its territory.

Clearly, these algorithms and their variants can be used by WYSIWYG, direct-manipulation formatters.

FrameMaker seems to provide the full functionality afforded by a one-pass greedy algorithm. A figure or table that must not or should not be split is put into a *frame*. One may *anchor* a frame to a particular point in the text, usually chosen by the user to be the point in the text that references the

contents of the frame. The three options for frame placement is that it appears:

1. at the top of the page containing the anchor,
2. just below the full line containing the anchor, or
3. at the bottom of the page containing the anchor.

A frame positioned according to choices 1 or 3, at the top or bottom of the page containing the anchor, moves only when the anchor moves to another page, taking the frame with it to the top or bottom of the new page. A frame positioned according to choice 2, just below the full line containing the anchor, is put there below the anchor if there is sufficient room on the current page for the frame. If there is not sufficient room on the current page for the frame, the frame is moved to the first subsequent page that has room at the top for the frame. The room at the top of a page may be reduced by another frame that is already there by virtue of its being positioned at the top of its page. If in addition, the frame has been designated as *floating*, the text that logically follows the frame is bubbled up to fill the space on the current page that was vacated by moving the frame to the next page.

The parts of Figure 7 show 5 steps in the life of a frame containing a figure or table as text is added above its anchor. In each part, the anchor for the frame is the upside-down 'T'. Note that in Step (a), in which the frame fits well within the first page, the text before the frame is all 'x' and the text below the frame is all 'y'. In Step (b), three lines containing all 's' have been added before the frame, pushing the three all-'y' lines to the next page, and the frame still fits within the dotted-line printing margin. In Step (c), one more line, containing all 'c', has been added before the frame, pushing the bottom of the frame to outside the printing margin. Step (d) shows FrameMaker having moved the frame to the top of the next page, and Step (d) shows FrameMaker having bubbled the all-'y' lines to after the anchor in the space on the first page vacated by the moved frame.

In FrameMaker, independently of the above, one can specify that text wrap around a frame that is not as wide as the page in which it sits, in order to make use of the space on either side of the frame.

Microsoft Word seems not to be as flexible as FrameMaker. Also in Word, a figure or table that must not or should not be split is put into a frame. A frame can be anchored to a point on a specific page or to a point in a specific paragraph. A frame anchored to a point on a specific page does not move as the text before it grows or shrinks. Rather the text flows around the frame. That is, lines are moved from before or after the frame to after or before the frame as the text before the frame grows or shrinks.

A frame anchored to a point in a paragraph will be put after that point if there is enough room for the frame on the current page. Unfortunately, the text after the frame is not automatically bubbled up to fill the space vacated by the moved frame. Moreover, there seems to be no way to force this bubbling to occur automatically. One way to achieve this bubbling is for the user to manually move the text after the frame to the space vacated by the moved frame. Another way to achieve the *effect* of bubbling is to anchor the frame to the page to which it will be moved. When the frame is so anchored, the text automatically flows around the frame. The drawback of this simulation of the desired behavior is that if the text that would have been the anchor is moved to another page, the figure is not moved. It's anchored to an absolute position. Under this circumstance, the user must move the figure manually to be anchored in the page that contains the text that would have been the anchor.

Recall the steps that FrameMaker follows through the parts of Figure 7. Basically, for a frame anchored to a point in a paragraph, Word does only Steps (a) through (d), leaving the space vacated by the moved frame to be dealt with manually.

In both FrameMaker and Word, independently of the anchoring of frames and whether or not bubbling is automatic, the user can specify that the text wrap around a frame to fill in the empty space to the side of the frame. When in addition, automatic bubbling occurs, it occurs through the wrapping text.

Further Information

More information about formatting algorithms can be found in Knuth's books about TEX (1986, 1988).

Text Mining

W Black, University of Manchester, Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

Text mining is the discovery of knowledge 'buried' in large collections of textual documents aided by computational methods; it is related to information retrieval (IR) (*see* **Document Retrieval, Automatic**) and information extraction (IE) (*see* **Information Extraction, Automatic**).

A classic example of text mining is the discovery by Swanson (1991) that magnesium deficiency is associated with migraine headaches using the (semi-)automated analysis of the titles of papers in the biomedical literature. The titles of the papers contained separate associations between pairs of concepts including stress, magnesium loss, calcium channel blockers, spreading cortical depression, platelet aggregability, and migraine patients, but in none was a direct link made between magnesium deficiency and migraine. After the discovery made through text analysis, the link was subsequently demonstrated clinically. Swanson described the mining scenario as "complementary research" and showed that the mining of associations between different literatures could yield more fruit in the biomedical sciences by publishing a succession of further similar discoveries.

The term 'text mining' was coined on the basis of a metaphor, and there is much scope for disagreement about what is and is not text mining. Several survey articles have sought to define the field, and to provide indexes to activities and resources in the area. One of these is Hearst (1999a), which compared and contrasted 'text mining' with the related terms 'data mining,' 'database query,' 'information retrieval,' 'computational corpus linguistics,' and 'information extraction.' Hearst pointed out that text mining often includes IE as a filtering step and also that many techniques used so far in text mining are similar to those of computational corpus linguistics. Text mining is done to discover knowledge that is useful for an application, in contrast to the automated acquisition of linguistic knowledge from texts to provide resources for natural language processing (NLP) applications. Common applications are business intelligence (Sullivan, 2001) and knowledge extraction from the literature of the biomedical sciences (Shatkay and Feldman, 2003).

Both Hearst (1999a) and Sullivan (2001) give more details about Swanson's complementary literature research.

Data Mining

The term 'text mining' has recently replaced the earlier 'text data mining,' which gives a clue to the origin of the term. Data mining, or knowledge discovery in databases (KDD), is the search for associations between types of occurrence recorded in databases and is usually associated with commercial applications, such as marketing. An example is the discovery from supermarket till data that those who buy diapers are disproportionately also likely to buy beer for home consumption. It turns out that these purchases are made by fathers, who now have fewer opportunities to socialize outside the home than they had when they were childless. Once this sort of association has been discovered, it can be used for various

Text mining is the discovery of knowledge 'buried' in large collections of textual documents aided by computational methods; it is related to information retrieval (IR) (*see* **Document Retrieval, Automatic**) and information extraction (IE) (*see* **Information Extraction, Automatic**).

A classic example of text mining is the discovery by Swanson (1991) that magnesium deficiency is associated with migraine headaches using the (semi-)automated analysis of the titles of papers in the biomedical literature. The titles of the papers contained separate associations between pairs of concepts including stress, magnesium loss, calcium channel blockers, spreading cortical depression, platelet aggregability, and migraine patients, but in none was a direct link made between magnesium deficiency and migraine. After the discovery made through text analysis, the link was subsequently demonstrated clinically. Swanson described the mining scenario as "complementary research" and showed that the mining of associations between different literatures could yield more fruit in the biomedical sciences by publishing a succession of further similar discoveries.

The term 'text mining' was coined on the basis of a metaphor, and there is much scope for disagreement about what is and is not text mining. Several survey articles have sought to define the field, and to provide indexes to activities and resources in the area. One of these is Hearst (1999a), which compared and contrasted 'text mining' with the related terms 'data mining,' 'database query,' 'information retrieval,' 'computational corpus linguistics,' and 'information extraction.' Hearst pointed out that text mining often includes IE as a filtering step and also that many techniques used so far in text mining are similar to those of computational corpus linguistics. Text mining is done to discover knowledge that is useful for an application, in contrast to the automated acquisition of linguistic knowledge from texts to provide resources for natural language processing (NLP) applications. Common applications are business intelligence (Sullivan, 2001) and knowledge extraction from the literature of the biomedical sciences (Shatkay and Feldman, 2003).

Both Hearst (1999a) and Sullivan (2001) give more details about Swanson's complementary literature research.

Data Mining

The term 'text mining' has recently replaced the earlier 'text data mining,' which gives a clue to the origin of the term. Data mining, or knowledge discovery in databases (KDD), is the search for associations between types of occurrence recorded in databases and is usually associated with commercial applications, such as marketing. An example is the discovery from supermarket till data that those who buy diapers are disproportionately also likely to buy beer for home consumption. It turns out that these purchases are made by fathers, who now have fewer opportunities to socialize outside the home than they had when they were childless. Once this sort of association has been discovered, it can be used for various

marketing purposes, for example, store design and direct-mail purchase recommendations.

In the fields of databases and management information systems, it is customary to refer to a pyramid in which data sit at the bottom, information lies above, and knowledge sits at the top. Data are the elementary facts recorded in the database, for example, that, in a given transaction, the customer purchased a six-pack of a particular brand of beer. Information is the higher-order facts based on aggregates of the simple data items; for example, knowing that the total sales of beer were up 12% on the previous week might inform a management decision about future purchases or sales promotions, whereas the raw data are only relevant operationally. Data and information can be extracted using a query language, such as SQL, to ask for either individual facts or functions such as the computing of means and sums over the individual facts. Knowledge, on the other hand, can be thought of as information that informs strategic rather than tactical decisions or as new information whose existence was previously unknown. Data mining, the activity of deriving knowledge from data and information, has been described as turning "what you didn't know you didn't know" into "what you know you know."

Association Mining

The association of two data values in a database is stronger the more frequently they occur together, but, if the two values occur separately as often as they do together, the association is less reliable. These aspects of the strength of association are captured in the two measures: *support* and *confidence*. If we label the values A and B, and write a putative association rule $A \Rightarrow B$, these measures can be defined, as in Figure 1, with respect to the transactions t in a data collection D. The support for the rule *diapers* $\Rightarrow$ *beer* is thus the proportion of transactions with {*diapers, beer*} as a subset in the data collection, and its confidence is the ratio of its support to that of just {*diapers*}.

Sequence Mining

A major application of data mining concerns the discovery of temporal patterns, called 'sequence mining.' Trends in values that change over time (time series) may be analyzed into components such as a long-term trend, cyclic and seasonal variations, and random movements. If these separate components can be estimated from a sample, the next movement in the series can be predicted.

Sequential pattern mining is the combination of time series analysis and association mining, in which we seek to discover relationships between different time series. An example is a fall of a given magnitude in one business sector's share prices followed, after a given interval, by a corresponding increase in a different sector.

$$support\,(A \Rightarrow B) = \frac{|\{t \in D : \{A, B\} \subseteq t\}|}{|D|}$$

$$confidence\,(A \Rightarrow B) = \frac{|\{t \in D : \{A, B\} \subseteq t\}|}{|\{t \in D : \{A\} \subseteq t\}|}$$

Figure 1 Definitions of the measures *support* and *confidence*.

Text Mining

Text mining is commonly understood, like data mining, to be an activity that reveals previously unknown knowledge from a large body of text. The individual operations that constitute text mining are as varied as those of data mining. One approach is to preprocess the text, using methods from IR and IE, to turn the textual data into a normalized database form and then to apply standard data-mining algorithms to the database. However, there are also extractive and exploratory techniques that can be applied directly to the text.

Document Warehousing

One difference between text mining and the similar-sounding concept IE is that text mining is conducted on a text collection, whereas IE can be conducted on one document at a time to provide a current-awareness information service. Text mining presupposes a large collection of texts organized uniformly and a system for procuring and managing the collection. In business, this is called a 'document warehouse' (Sullivan, 2001). Among the basic functions that precede mining for interesting knowledge are document collection (e.g., by Web crawling), document conversion from diverse formats to a common annotation scheme, low-level text processing (e.g., tokenization and sentence splitting; Palmer, 2000), part-of-speech tagging, and morphological analysis or stemming. Indexes are created, as in a standard full-text information retrieval system. Sullivan also considered document summarization to be a basic function in a document warehouse.

Mining Operations

Feature Extraction

Commercial tools describe IE and term discovery (Fagan, 1987; Franzi and Anaiadou, 1999) as feature extraction. Both types of technique have been used to

collect textual instances (and variants) of protein and gene names, as well as business names. Term variance is a significant problem in the scientific literature, and dynamic programming (as used in example-based machine translation and in gene sequencing; see Sankoff and Kruskal, 1999) has been deployed to find equivalences between complex terms and acronyms. Consider the conference whose acronym is *NeMLaP*. It can be aligned with the full text name as shown in Figure 2. Two sequences are compared by counting the cost of changing one to the other. Individual insertions, deletions, and substitutions each have a cost, and the costs of different kinds of change can have their own coefficients. In matching acronyms with phrases, the cost of substituting a word with its initial letter, capitalized, is set low, whereas the substitutions of later letters can be penalized. Variants on this scheme can also detect the similarity of reorderings of the words in a compound name.

Classification and Clustering

Given a large document collection, an obvious question to ask is what topics it covers. To find a useful answer, a technique will look for patterns of similarity and difference of content throughout the collection. Two fundamental techniques applicable here and provided by most text-mining software packages are text classification (*see* **Classification of Text, Automatic**) and document clustering. Text classification involves mapping each text to one or more predetermined categories. Frequently, however, the text miner does not wish to make assumptions about how documents should be classified but prefers to discover patterns by unsupervised learning. Document clustering (Everitt, 1980) groups together the documents found to be most alike, comparing vectors of the documents' term frequencies with one another. Variants of clustering produce disjoint or hierarchical clusters or use a neural network to form a self-organizing map (SOM; see Merkl, 2000). Clusters can be visualized (Hearst, 1999b) or can be used behind the scenes in query processing, as described by Baeza-Yates and Ribeiro-Neto (1999).

Using and Extending Ontologies

Feature extraction typically involves matching text strings with the names of known entities as well as pattern matching. If the background knowledge is a simple gazetteer, which maps these strings to a category, then extraction results merely in a classified set of extracted strings. However, if the background knowledge is an ontology linked to a synonym dictionary, the features extracted can be instances in a knowledge base. Many document warehouses annotate documents with ontology-linked metadata (as with the Semantic Web), either by automatic feature extraction or manually. Ontologies are also useful for classified browsing of a document collection, but are expensive to develop and maintain if constructed by intellectual effort. There is considerable interest in the automatic discovery of concepts and conceptual relations, and state-of-the-art approaches use clustering (of words and phrases rather than documents) as well as syntactic pattern extraction (Grefenstette, 1994).

New Methods in Language Processing
Ne__M_____La_____P_____

Figure 2 Aligning the acronym *NeMLaP* with its full text name.

Combining Text and Data Mining

Because the focus of both text and data mining is extracting applicable knowledge from data collections, it is increasingly common to link both textual and nontextual data to generate insights from the relation between the two. Lavrenko *et al.* (2000) reported a text-mining experiment in which stock price movements were analyzed into discrete trends and news stories featuring those stocks were analyzed to generate a Bayesian language model. The model was shown to generate investment recommendations that would produce modest gains, out-performing a random investment strategy. Shatkay and Feldman (2003) reported several studies in which documents from the scientific literature were aligned with gene-sequence data in order to discover gene functions. de Bruin and Martin (2002) defined 'literature mining' or 'automated reading' as a process involving four general subtasks: text categorization, named entity tagging, fact extraction, and collectionwide analysis. The first three are NLP techniques, and the last uses data mining. Clifton *et al.* (2004) showed how the market-basket analysis technique of association mining described here can be used, in combination with prior information extraction, to produce structured topic signatures made of class-labeled named entities that can then be used to identify collectionwide trends in topic salience.

Text Retrieval Conference

Introduction

Document retrieval (*see* **Document Retrieval, Automatic**) has a long history of evaluation, starting in the early 1960s with small test collections of abstracts and sample search questions (with answers). These collections enabled the testing and development of the early statistical methods for document retrieval (a research field often called information retrieval). With the advent of larger computers, and much larger amounts of computerized text, these early test collections became too small to serve the research community, but there was no funding available to build larger ones.

In 1990 the National Institute of Standards and Technology (NIST) was asked to build a very large test collection to enable evaluation of the document (text) retrieval technology being developed as part of the DARPA TIPSTER program (Merchant, 1996). This collection was to be on the order of one million full-text documents: about 100 times larger than the existing nonproprietary test collections for document retrieval. Once the collection was built, NIST proposed that it be made available to the full research community by the formation of the Text Retrieval Conference (TREC) (Voorhees and Harman, 2005). This conference was envisioned to be more than just a workshop; by providing a large test collection, uniform scoring procedures, and a forum for organizations interested in comparing results, it was hoped that comparison across a much wider variety of techniques than any one research group could tackle would be possible.

Since 1992 there have been multiple TREC conferences, co-sponsored by NIST, ARDA, and DARPA, with the number of participating systems growing from 25 in TREC-1 to over 100 in 2004, including participants from more than 15 different countries. The diversity of the participating groups has ensured that TREC represents many different approaches to text retrieval, and the emphasis on individual experiments evaluated in a common setting has proven to be a major strength. Each of the conferences has produced a proceedings containing papers from participating groups giving the details of their experiments.

The initial task in the early TRECs, called the *ad hoc* task, tested the ability of systems to retrieve

Text Retrieval Conference

Introduction

Document retrieval (*see* **Document Retrieval, Automatic**) has a long history of evaluation, starting in the early 1960s with small test collections of abstracts and sample search questions (with answers). These collections enabled the testing and development of the early statistical methods for document retrieval (a research field often called information retrieval). With the advent of larger computers, and much larger amounts of computerized text, these early test collections became too small to serve the research community, but there was no funding available to build larger ones.

In 1990 the National Institute of Standards and Technology (NIST) was asked to build a very large test collection to enable evaluation of the document (text) retrieval technology being developed as part of the DARPA TIPSTER program (Merchant, 1996). This collection was to be on the order of one million full-text documents: about 100 times larger than the existing nonproprietary test collections for document retrieval. Once the collection was built, NIST proposed that it be made available to the full research community by the formation of the Text Retrieval Conference (TREC) (Voorhees and Harman, 2005). This conference was envisioned to be more than just a workshop; by providing a large test collection, uniform scoring procedures, and a forum for organizations interested in comparing results, it was hoped that comparison across a much wider variety of techniques than any one research group could tackle would be possible.

Since 1992 there have been multiple TREC conferences, co-sponsored by NIST, ARDA, and DARPA, with the number of participating systems growing from 25 in TREC-1 to over 100 in 2004, including participants from more than 15 different countries. The diversity of the participating groups has ensured that TREC represents many different approaches to text retrieval, and the emphasis on individual experiments evaluated in a common setting has proven to be a major strength. Each of the conferences has produced a proceedings containing papers from participating groups giving the details of their experiments.

The initial task in the early TRECs, called the *ad hoc* task, tested the ability of systems to retrieve

Number: 168
Topic: Financing AMTRAK

Description:
A document will address the role of the Federal Government in financing the operation of the National Railroad Transportation Corporation (AMTRAK).

Narrative:
A relevant document must provide information on the government's responsibility to make AMTRAK an economically viable entity. It could also discuss the privatization of AMTRAK as an alternative to continuing government subsidies. Documents comparing government subsidies given to air and bus transportation with those provided to AMTRAK would also be relevant.

Figure 1 Sample topic statement from TREC-3.

accurate and complete ranked lists of documents in response to fifty information-need statements (see Figure 1 for an example). The task is similar to how a researcher might use a library or a person might search the web. NIST provided the participants with approximately 2 GB of documents and a set of 50 natural language information-need statements (called 'topics' in TREC), and participants returned a ranked list of the top 1000 documents retrieved for each topic, using either automatic or manual methods for producing this list. TREC has followed traditional evaluation methodology for information retrieval; that is, the building of test collections, and evaluation of system results against human judgments. The two major measures used have been precision (percent of system results that are correct) and recall (percent of total correct answers that a system retrieves).

TREC Test Collections

The creation of a set of large, unbiased test collections has been critical to the success of TREC. Like most traditional information retrieval collections, there are three distinct parts to these collections – the documents, the information-needs (topics), and 'right answers' (relevance judgments). The documents are mostly from the news domain, including newspapers and newswire (such as the *Wall Street Journal* and Associated Press). Figure 1 shows one of the TREC topics, illustrating the three main parts to this topic. Each topic has a short title, followed by a (usually) one-sentence description, and finally followed by a much more detailed description of the particular information the user is seeking.

For each topic it is necessary to compile a list of relevant documents – as comprehensive a list as possible. TREC uses a sampling method known as pooling that takes the top N (usually 100) documents retrieved by each system for a given topic and merges them into a pool for relevance judgment. The merged list of results is then shown to the human judges; for example, in TREC-6 there was an average of 1445 documents judged per topic, with about 6% or 92 of these found relevant (Voorhees and Harman, 2000). All of these collections have been made available to the public and are heavily used throughout both the commercial and academic communities.

Additional TREC Tasks

Starting in TREC-4, secondary tasks have been added to TREC. These tasks have either been related to the *ad hoc* task, or have involved completely new areas of research that are related to text retrieval. Below is a brief summary of some of the larger (and longer-running) tasks.

1. Routing/Filtering (1992–2002): given some training material, i.e., relevant documents, find additional relevant documents from new incoming text.
2. Interactive (1994–2003): a task used to study user interaction with text retrieval systems.
3. Spanish (1994–1996) and Chinese (1995–1997): an *ad hoc* task with topics and documents in Spanish or Chinese.
4. Cross-language (1997–2002): an *ad hoc* task to retrieve documents from many languages (such as English, French, German and Italian), using topics in only one language. Additionally this track has been run bilingually from English to Chinese (2000) or Arabic (2001–2002).
5. Spoken Document (1997–2000) and Video (2001–2004) retrieval: an *ad hoc* task using broadcast news or video segments, respectively, as the target documents.
6. Very Large Corpus (1997–2000) and Web (1999–2004): an *ad hoc* task investigating the ability of retrieval systems to handle larger amounts of data (over 100 GB). Special web retrieval tasks have also been run using web samples such as the .gov domain.
7. Question-Answering (1999–2004): an *ad hoc* task in which the systems provide the answers to the topics/questions as opposed to just a ranked list of documents.

The introduction of the various tasks has led to research in new areas of text retrieval. The cross-language retrieval tasks were the first (large-scale) formal testing of retrieval systems in languages other than English and have led to expanded formal evaluations in both Europe (called CLEF) and Asia (called NTCIR). The Spoken Document, Video, and Question-Answering tasks have joined the speech recognition, video, and the natural language

processing communities to the text retrieval community, allowing rich interaction.

For further information on TREC, see the cited references and the TREC web site, which contains online proceedings from each TREC, information on how to get the test collections, and news on ongoing TREC activities.

Message Understanding Conference

Introduction

Information extraction (*see* **Information Extraction, Automatic**) differs in many distinct ways from information retrieval. The goal of the task itself is different in that specific information, such as names, dates, relationships, etc., are to be extracted from documents, as opposed to information retrieval where the goal is to retrieve documents with respect to some user input. The research communities in these two areas come from different backgrounds and training, with the information extraction community drawn largely from groups working in natural language processing. And finally, whereas information retrieval has had standard evaluation procedures since the early 1960s, widespread evaluation in the information extraction community did not start until the 1990s, and this evaluation sprang from the Message Understanding Conference (MUC).

MUC was started in 1987 as a U.S. Navy project at the Naval Ocean Systems Center (NOSC) to investigate the state-of-the-art for message understanding systems, i.e., systems that could process natural language text into some type of structured representation. Twelve organizations participated in a workshop (initially called MUCK), processing with a common set of 10 messages dealing with ship sightings and engagements and comparing notes on the meaning interpretations produced by their systems. Two years later MUCK-II worked with similar messages, but with a clearly defined task, namely to fill a template with event-related information from the messages. A rudimentary quantitative evaluation was made of the systems' ability to produce the expected template fills.

Formalization of Evaluation Methodology

MUC-3 (1991) was sponsored by DARPA and attracted 15 groups through an open call for participation. The evaluation (Chinchor *et al.*, 1993) was considerably more complex than the earlier ones and the domain was much broader, moving from naval messages on highly constrained topics to the general topic of terrorist activity in Latin America. The texts were full text articles of various genres (news stories, political speeches, rebel communiqués, etc.) taken mostly from translations of Spanish-language print and broadcast news sources, with a training corpus of 1300 articles and three test sets containing 100 articles each.

Table 1 MUC-3 answer key template example

0. MESSAGE ID	TST1-MUC3-0080
1. TEMPLATE ID	1
2. DATE OF INCIDENT	03 APR 90
3. TYPE OF INCIDENT	KIDNAPPING
4. CATEGORY OF INCIDENT	TERRORIST ACT
5. PERPETRATOR: ID OF INDIV(S)	''THREE HEAVILY ARMED MEN''
6. PERPETRATOR: ID OF ORG(S)	''THE EXTRADITABLES''/ ''EXTRADITABLES''
7. PERPETRATOR: CONFIDENCE	CLAIMED OR ADMITTED: ''THE EXTRADITABLES''/ ''EXTRADITABLES''
8. PHYSICAL TARGET: ID(S)	*
9. PHYSICAL TARGET: TOTAL NUM	*
10. PHYSICAL TARGET: TYPE(S)	*
11. HUMAN TARGET: ID(S)	''FEDERICO ESTRADA VELEZ''(''LIBERAL SENATOR'')/ ''ANTIOQUIA DEPARTMENT LIBERAL PARTY LEADER'' /''SENATOR''/''LIBERAL PARTY LEADER''/''PARTY LEADER''
12. HUMAN TARGET: TOTAL NUM	1
13. HUMAN TARGET: TYPE(S)	GOVERNMENT OFFICIAL/POLITICAL FIGURE: ''FEDERICO ESTRADA VELEZ''
14. TARGET: FOREIGN NATION(S)	–
15. INSTRUMENT: TYPE(S)	*
16. LOCATION OF INCIDENT	COLUMBIA: MEDELLIN (CITY)
17. EFFECT ON PHYSICAL TARGET(S)	*
18. EFFECT ON HUMAN TARGET(S)	–

The task performed in MUC-3 was to find all terrorist events that occurred in the articles and to extract 18 specific types of information for each event, such as event type, e.g., bombing, date of the event in canonical form, and specific strings from the text, such as the perpetrator of the event. This information was to be output in a template, with one slot for each of the 18 types of information (see Table 1 for an example).

An automated scoring program was centrally administered, incorporating metrics of precision (percentage of correct fills over total fills) and recall (percentage of correct fills over the expected fills based on the answer keys prepared by NOSC). MUC-4 (1992) continued in the Latin American terrorist domain, with fresh data and a more complex template design, plus the establishment of the F-measure as a unified recall-precision metric.

MUC-5 (1993) was a major part of the DARPA TIPSTER program. There were two domains, joint ventures and microelectronics, to allow systems to investigate issues of domain independence, and two languages, English and Japanese, for investigation of language differences. This resulted in four corpora, each about the size of the MUC-3 corpus. The template structure consisted of nested objects, starting with a single top-level template per document, and including slots to point between related objects, with extensive written guidelines for the correct filling of these templates. Eighteen groups completed at least one of the four evaluation tasks, and despite the increase in complexity of the task, groups in general matched or exceeded the MUC-4 scores. Results in Japanese were surprisingly good, often surpassing results in English (Sundheim, 1993).

Movement Toward More General IE Goals

There was a general feeling among the research groups that MUC needed to move towards more general information extraction goals. MUC-6 (Grishman and Sundheim, 1996) (1996) had four tasks, designed to demonstrate task-independent component technologies which would be immediately useful, encourage work to make systems more portable, and encourage work on deeper understanding of natural language. The named entity extraction task, defined as an in-line SGML annotation task, was a major success, with most of the 15 participating groups able to achieve recall and precision over 90%.

Simplified continuations of the template-filling task, with a domain-neutral template element and a scenario template consisting of a three-level object structure (an event level, a relational level, and the template element level) demonstrated that systems could obtain reasonable performance with acceptable amounts of time to port the system to the target domain. The fourth task, that of locating co-references for nouns, noun phrases and pronouns, addressed the desire for deeper understanding of natural language.

MUC-7 (1997) built on the strengths (and tasks) of MUC-6. The named entity task was run in English, Japanese and Chinese, with scores still about 90% in all three languages. The definition of the co-reference task was made sharper. Three different types of template designs were implemented, including the template element and scenario template from MUC-6, and a new, small template to capture relationships between pairs of entities (template element structures).

MUC-7 was the last in the MUC series, with no further MUCs being planned. The Automatic Content Extraction (ACE) evaluations (Doddington *et al.*, 2004) continue exploration of the information extraction arena.

The legacy of MUC is both a powerful evaluation framework for information extraction, in particular for the template-filling task, and the establishment of a large community of natural language processing researchers situating their work firmly within these established evaluation practices. The trend toward heavier use of statistical methods, as opposed to mostly hand-built rule sets and structures, owes a large debt to sizable amounts of gold standard outputs and solid evaluation methodologies that came from MUC. And finally, the commercialization of some information extraction techniques, such as named entity extraction, is due directly to successes in MUC.

Text World Theory

J Gavins, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

'Text World Theory' is an attempt to unify a number of key ideas about human discourse processing under one analytical framework. Its structure is drawn from a range of diverse disciplines, including possible-worlds logic, discourse analysis, cognitive psychology, cognitive linguistics, and stylistics. The original text-world framework was formulated by Paul Werth during the 1990s, primarily in relation to literary fiction (e.g., Werth, 1994, 1995a, 1995b, 1999). More recently, Text World Theory has been further developed and applied to a broad range of both literary and nonliterary discourses (e.g., Gavins, 2000, 2003, 2006; Hidalgo Downing, 2000; Stockwell, 2002). The basic theoretical premise underlying Text World Theory is that human beings understand discourse by constructing mental representations, or 'text worlds', of it in their minds. The practical aim of the theory is to provide an accurate account of human communication processes, in all their cognitive and psychological complexity. This necessarily means investigating both the discourse itself and the context surrounding its production and reception.

Text World Theory approaches this considerable task by splitting human communication into three manageable levels: the 'discourse world,' the 'text world,' and the 'subworld' (Werth, 1994, 1995a, 1995b, 1999). The first of these levels, the discourse world, deals with the immediate situation surrounding at least one speaker or writer and one or more listeners or readers. These sentient beings are referred to in Text World Theory as the 'participants,' the conscious presence of whom is essential for a discourse world to exist. This is because the discourse world includes not only the participants and the objects and entities that surround them, but all the personal and cultural knowledge that the participants bring with them to a language situation. This knowledge is of central importance to our understanding of human communication, since it has the potential to impact upon both the construction and comprehension of a given discourse. The majority of preceding approaches to discourse study have fought shy of dealing with context, mainly because of the fact that its unwieldy nature at first appears incompatible with rigorous linguistic analysis. Text World Theory, on the other hand, introduces the principle of 'text-drivenness' to provide a manageable route into the systematic examination of context. This principle specifies that, from the vast store of personal knowledge and experience available to the participants, it is the **text** produced in the discourse world that determines which areas are needed to process and understand the discourse at hand. When discussing recent film releases with friends, for example, we need only activate this area of our knowledge. Our experiences of cake decoration or crossing the road remain redundant, unless specifically referred to in the course of the conversation.

Every time a new act of communication occurs, a new and unique discourse world comes into being, the contents and structure of which will depend greatly on the nature of the communication in question. In face-to-face communication, for example, the participants share the same physical space and are able to refer directly to objects and entities in the immediate surroundings. Other nonlinguistic factors, such as body language and intonation, will also play a part in the structure of the discourse and the relative ease with which it is comprehended. There are a number of situations in which the discourse world will be split between two, or even more, spatial and temporal locations. The participants in telephone communication or internet chat room conversation, for example, normally share a temporal location (except in the

Text World Theory

J Gavins, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

'Text World Theory' is an attempt to unify a number of key ideas about human discourse processing under one analytical framework. Its structure is drawn from a range of diverse disciplines, including possible-worlds logic, discourse analysis, cognitive psychology, cognitive linguistics, and stylistics. The original text-world framework was formulated by Paul Werth during the 1990s, primarily in relation to literary fiction (e.g., Werth, 1994, 1995a, 1995b, 1999). More recently, Text World Theory has been further developed and applied to a broad range of both literary and nonliterary discourses (e.g., Gavins, 2000, 2003, 2006; Hidalgo Downing, 2000; Stockwell, 2002). The basic theoretical premise underlying Text World Theory is that human beings understand discourse by constructing mental representations, or 'text worlds', of it in their minds. The practical aim of the theory is to provide an accurate account of human communication processes, in all their cognitive and psychological complexity. This necessarily means investigating both the discourse itself and the context surrounding its production and reception.

Text World Theory approaches this considerable task by splitting human communication into three manageable levels: the 'discourse world,' the 'text world,' and the 'subworld' (Werth, 1994, 1995a, 1995b, 1999). The first of these levels, the discourse world, deals with the immediate situation surrounding at least one speaker or writer and one or more listeners or readers. These sentient beings are referred to in Text World Theory as the 'participants,' the conscious presence of whom is essential for a discourse world to exist. This is because the discourse world includes not only the participants and the objects and entities that surround them, but all the personal and cultural knowledge that the participants bring with them to a language situation. This knowledge is of central importance to our understanding of human communication, since it has the potential to impact upon both the construction and comprehension of a given discourse. The majority of preceding approaches to discourse study have fought shy of dealing with context, mainly because of the fact that its unwieldy nature at first appears incompatible with rigorous linguistic analysis. Text World Theory, on the other hand, introduces the principle of 'text-drivenness' to provide a manageable route into the systematic examination of context. This principle specifies that, from the vast store of personal knowledge and experience available to the participants, it is the **text** produced in the discourse world that determines which areas are needed to process and understand the discourse at hand. When discussing recent film releases with friends, for example, we need only activate this area of our knowledge. Our experiences of cake decoration or crossing the road remain redundant, unless specifically referred to in the course of the conversation.

Every time a new act of communication occurs, a new and unique discourse world comes into being, the contents and structure of which will depend greatly on the nature of the communication in question. In face-to-face communication, for example, the participants share the same physical space and are able to refer directly to objects and entities in the immediate surroundings. Other nonlinguistic factors, such as body language and intonation, will also play a part in the structure of the discourse and the relative ease with which it is comprehended. There are a number of situations in which the discourse world will be split between two, or even more, spatial and temporal locations. The participants in telephone communication or internet chat room conversation, for example, normally share a temporal location (except in the

case of telephone answering machine messages) but not a spatial one. The discourse worlds of written communication, on the other hand, are often split both spatially and temporally, sometimes over many thousands of miles and many hundreds of years. Some discourse worlds (the reading of a novel, for example) may continue over many months, in a variety of different locations, while others (a passing nod on a crowded train) may be fleeting and minimally detailed. In each case, however, the context surrounding the participants, whether shared or separate, is of paramount importance in the processing of the discourse. Consider, for example, the differing experiences of reading Cædmon's hymn from a projector screen in a lecture hall in New York and reading it from a carved stone crucifix on a cliff top in Whitby, England.

As the participants in the discourse world communicate with one another, they construct mental representations of the discourse in their minds, in which the language being produced can be conceptualized and understood. These mental representations are known as 'text worlds.' The deictic and referential expressions included within a text establish the spatial and temporal boundaries of the text world and specify whether any entities or objects are present. These details, known as the 'world-building' elements of the text, can be seen to form a kind of static conceptual background against which certain activities and descriptions may be played out. These activities and descriptions are known as the 'function-advancing' elements of the text world, the precise nature of which will vary depending on the type of text involved. In narrative texts, for example, actions and events are often in abundance, the function of which is to propel the narrative forward. The function-advancing elements of an instructive text, on the other hand, are likely to include a greater number of imperatives, and so on.

Once a text world has been created, any number of departures from its initial world-building parameters may occur during the discourse process. These departures cause new worlds to be created in the minds of the participants. They constitute the third and final layer of Text World Theory and are known as 'sub-worlds.' A subworld may be created by one of the participants at the discourse-world level. In such cases, the participants are free, particularly in face-to-face communication, to question one another's statements and to clarify any aspect of the discourse they do not understand. When entities at the text world level (referred to as 'characters' in Text World Theory) communicate, however, the reliability of the worlds they create cannot be assessed according to the same criteria as those produced in the discourse world. In Text World Theory terms, worlds created by the participants are 'participant-accessible,' while worlds created by characters are only 'character-accessible.' This logical distinction is one basically drawn between the different ways the participants process worlds created at the different conceptual levels of the framework, and explains why, in some cases, judgment may be reserved on the dependability of the contents of a particular world.

Sub-worlds are created for a variety of reasons but generally fall into one of two broad categories. 'World-switches' (Gavins, 2003, 2006) occur when the temporal or spatial parameters of the text world change. The text may flash backward or forward to a different time zone, or it may switch the spatial location of the world as a concurrent scene is referred to or described. Changes in the temporal parameters of a world often occur in conjunction with a change in the spatial parameters as well. Instances of direct speech and direct thought representation may also cause a world-switch, as present-tense discourse is injected into a past-tense narrative. In each case, a new world is created appropriate to the new time or scene.

Slightly more complex are 'modal worlds' (Gavins, 2003, 2006), which occur whenever some form of modalization is used in a discourse. Modal expressions are usually separated into three categories: 'deontic,' 'boulomaic,' and 'epistemic.' In Text World Theory, the use of each of these creates a corresponding modal world. Deontic modal worlds are created whenever a degree of obligation is attached to a proposition. For example, if I say that someone '**must** keep off the grass' or that they '**should** do the washing up,' a new world is created in which the activity of 'keeping off the grass' or 'doing the washing up' is taking place. Although a participant or character may be expressing their **attitude** to such propositions in the discourse world or the text world, the activities themselves are, as yet, unrealized. A separate, modal world must therefore be created for us to conceptualize both the activity and the world-creator's attitude toward it. Boulomaic modal worlds operate in a similar manner. Whenever a speaker or writer expresses a degree of desire, a separate modal world is created in which the proposition in question can be conceptualized. For example, if I say 'I **wish** I had more days in the week,' the boulomaic modal verb 'wish' causes a new world in which 'more days in the week' exist. This situation is, of course, unrealized and therefore remains in a mental space separate from the main discourse.

Epistemic modal worlds allow us to conceptualize expressions of remoteness in discourse and can occur for a number of different reasons. Instances of

indirect speech, indirect thought, and free indirect discourse all filter a text, however fleetingly, through a new perspective. This perspective thus creates a new world in which the resulting epistemic distance from the initial speaker or writer can be fully conceptualized. Focalized narration in written discourse has a similar effect, since readers are aware throughout that their only access to the text world is through the mind of a character who may or may not be participating in the unfolding events. The character-accessibility of such modal worlds is frequently manipulated by literary authors to create disorienting or deliberately misleading narrative effects. Hypotheticals also cause modal worlds to be created, since they necessarily depict unrealized events at some epistemic distance from the text world. Finally, conditional constructions require separate worlds for us to conceptualize the remote situations they describe. In the sentence 'If you see Paul, tell him he owes me a fiver,' for example, the 'if' marker signals the construction of a remote situation in which the addressee comes into contact with Paul. The 'tell him he owes me a fiver' section of the conditional can be seen to advance this modal world further by providing added detail of the possible future events concerned.

The main application of Text World Theory to date has been to literary discourse (e.g., Gavins, 2000, 2003; Hidalgo Downing, 2000; Stockwell, 2002; Werth, 1994, 1995a, 1995b, 1999), where it provides a systematic framework for investigation of the conceptual structures involved in the processing of certain poetic and narrative devices. Increasingly, however, Text World Theorists are finding new and fruitful ground in nonliterary discourses as diverse as family arguments, verbal directions, media discourse, and Web authoring (Gavins, 2006).

Texts: Semiotic Theory

P Colilli, Laurentian University, Sudbury, Ontario, Canada

The concept of the 'text' as the artifact generated by a signifying system and open to inquiry has been of singular importance for literary and cultural studies. In a more general sense, the idea of text is the most essential datum upon which a considerable amount of research dealing with signifying systems is based. M. Bakhtin claims that the notion of text is "the primary datum of the human sciences ... the immediate reality (reality of thought and of experience) within which this thought and these disciplines can exclusively constitute themselves. Where there is no text, there is neither object of inquiry nor thought" (Bakhtin, 1986: 103ff.). Textuality could be understood as a cultural product composed of the remains left behind or deposited by the process of semiosis. Moreover, a text is something from which the event of communication can be extracted. Ultimately, a semiotic theory of texts operates as a subcategory of the general science of signs, and has as its premise the same principles and paradigms as the semiotics of verbal discourse.

However, establishing the boundaries and limits of, for example, the semiotics of the literary text is problematic. The scope of what is considered 'literariness' is more the result of tradition and practices than of

more formal theories and rule. Unlike other semiotic discourses such as, for example, economic discourse, literary discourse cannot be qualified by a distinctive content. The difficulty arises because the literary quality of a text can vary depending upon the culture and the time period. A text identified as being scientific or philosophical in the Renaissance is understood as being a literary work in a subsequent age. Moreover, there is a debate concerning the verbal sign and the status of the signifying process. The issue is whether to adopt an intentional, or meaning-oriented description of a sign system within a given content or to employ a more global, truth-condition-oriented one that focuses on the signifying process whereby signs are deployed to refer to other signs situated in the real or in a given possible world.

Within the context of a traditional notion, a text is defined as that part of a work that is separate and distinguished from the parts that are close and related to it. Namely, endnotes, commentary, bibliographic references, the page numbering, the data concerning publication and other typographic elements. Such an understanding of the term *text* is linked to its Latin etymology *textus*, which is derived from *texere* 'to weave.' The traditional notion conserves the understanding of a sample of writing as constituting an entire cloth that cannot be partitioned. From this perspective the adjective *original* is often used when dealing with the idea of a text. Textual scholars aim to reconstruct the original text, with the intent of establishing the grounds for interpretations that adhere to a measure of authenticity. Structuralism altered the understanding of the word *text*, in that it was connected to the distinction between *langue* (a language system) and *parole* (the particular utterances produced by the *langue*). Consequently, *text* can be used together with the words *message* and *code* as a way to designate one mode in which signs are constructed in a pragmatic fashion. The word 'text' is frequently used in ordinary language with the implication of an artifact characterized by temporally limited typicality and constituted by combinations and segmentations of time-bound elements such as words, phonemes, graphemes, grammatical rules, and so on.

A 'classic' of semiotics is the work of Charles Morris, which is useful in understanding the semiotic theorizations about texts. For Morris semiosis is a process where signs function as vehicles, interpretants, and interpreters. To this triad of correlates Morris adds a further segmentation of semiosis consisting of (1) syntactics, which analyzes the relation linking one sign vehicle to another one; (2) semantics, which analyzes the relation of signs to objects they represent; and (3) pragmatics, which analyzes the relation between signs and their interpreters (see Nöth, 1995: 50). Consequently, if one studies texts in terms of semiosis, they can be understood as syncretic sign systems that feature a syntactic segment that can be studied from the point of view of phonology and narrative syntax; the semantic dimension (the text's content), as well as the pragmatic or communicative dimension. In essence, the first two aspects underline the text's structural components and deal with their articulation and content forms, while the other aspect underlines the signifying process and focuses on studying their generative processes and interrelations with other texts (Sebeok, 1986: 453–454).

According to M. A. K. Halliday, the semantic system is part of a triad of segments that makes up the linguistic system, the other two being the lexicogrammatical and the phonological. The semantic system itself consists of four elements: the experimental, the logical, the interpersonal, and the textual. Whatever gives rise to text is structured as the expression of all four elements. In his analysis of the nature of text, Halliday does not accept the idea that text is a variety of super-sentence, that is, an object that is greater than a sentence but of the same type. Rather, sentences realize text instead of constituting it, thus establishing text as a semantic concept with a generic structure (Halliday, 1977: 194). Text is perceived as an ongoing process of semantic choice; it is meaning and meaning is choice, a continuous flux of selections (195). A text is realized lexicogrammatically and phonologically, that is, in the lower levels of the linguistic system. Moreover, a text is also the realization of higher segment signifying processes that possess their own means of interpretation, namely, the literary, the sociological, the psychoanalytic, and so on. However, a key element in Halliday's theory is that the social system invents the meanings that its members exchange through the medium of the text, which mirrors "resistance and change in the social system" and remains "the primary channel of the transmission of culture" (Halliday, 1977: 199).

Fredric Jameson observes that textuality has become a "methodological hypothesis whereby the objects of study of the human sciences are considered to constitute so many texts that we decipher and interpret, as distinguished from older views of these realities or existents or substances that we in one way or another attempt to know" (Jameson, 1987: 18). Precisely because the materiality of the text is an intricate structure that distinguishes it from a given context, the concept of the text forces us to consider that the items under investigation are never a datum. If anything, we need to carefully consider the manner in which they were produced, isolated, presented to attention. In fact, for any text, we must think about

signification itself as a problem, rather than as a given. This means that we need to investigate the analysts' methods "not just prior to the inquiry to decide what will be done, but in the process of considering the objects of study themselves" (Culler, 2001: 441). As far as how a text presents itself or is transmitted to posterity is concerned, we can say with Seth Lerer (who is here talking about the English literary tradition) that "to historicize its notion of the author, its conception of the reader, and its idioms of genre, form, and social purpose – is to understand primarily its self-conscious articulation of its modes of making and its media of transmission" (Lerer, 2003: 1253). This notion is closely linked to what John Guillory states about canon formation: "Canonicity is not the property of the work itself but of its transmission, its relation to other works in a collocation of works" (Guillory, 1993: 136).

Texts assimilate the structural characteristics of the signifiers with which they are composed, however, it does not follow that they are conceptually equivalent to the sum of their signifieds. A poem, for example, consists of words that are placed in a series or sequence; but the poem is not merely the total aggregate of the meanings of words. It is for this reason that a poem is interpreted not by focusing solely on its individual structural components, but by conceiving the poem as a single sign. This reasoning achieves a more expansive sense if we foreground it with the semiotic theory of composite modeling proposed by Thomas A. Sebeok and Marcel Danesi, according to whom.

> [C]omposite modeling is the activity of representing complex (nonunitary) referents by combining various signifiers in some specifiable way. Drawings, narratives, theories, conversations, etc., are all examples of composite forms of representation. These are constructed with distinct signifiers that fit together structurally, but which are, as a whole, different from any of their constituent signifiers taken individually. In analogy to atomic theory, a singularized form can be compared to an atom and a composite form to a molecule made up of individual atoms, but constituting a physical form in it own right (2000: 28–29).

Janos Petöfi qualifies textuality as "a property assigned by the analyzer to a linearly ordered object with a basic constituent consisting solely of verbal signs, or having a dominating verbal kern, if it meets the definitory criteria of the analyzer" (1986: 1081). Petöfi adds the following elements to describe some of the main aspects of the definition of texts or discourses:

1. The object consists exclusively of (written or oral) verbal signs, or the object also contains, in addition to (written or oral signs) verbal signs, gestures as its constitutive elements, or the object is made up of arbitrary elementary objects considered as signs.
2. The object is a physically given natural object (a written text, a communicative act recorded on audio- or video-tape, or a configuration of different communicative acts), or the object is a theoretical construct.
3. The object is a linearly-ordered configuration of objects considered as elementary signs, or the object is a nonlinearly-ordered configuration of objects considered as elementary signs.
4. The object is a configuration of objects considered as signs that exceed a certain size, or the object can be considered, as a completed functional unit, regardless of its size (Petöfi, 1986: 1080).

According to Petöfi, a text can be analyzed in a triadic fashion; namely, as (1) a co-textual sequence of signs, (2) a con-textual sequence of signs, (3) a text (1986: 1081). Co-textual investigation refers to, in the specific ambit of a sentence structure, the analysis of the grammatical structure. Con-textual analysis refers to, within the context of a single sentence, investigating the parameters making up the contexts along with the analysis of the speech acts and the specific convention of the different registers. In contextual analysis the interpretative paradigms of sociolinguistics, ethnolinguistics, and pragmalinguistic theory recite a key role. Textual analysis is concerned foremostly with issues and questions pertaining to the interpretability of a specific text.

Daniel Chandler's reflections on the textual fabric of signification encourages us to observe that, in general, a text can be characterized as a network of signs constructed in adherence to codes and subcodes in which we find ingrained cultural practices, beliefs, and values. If anything, codes go beyond specific and separate texts connecting them in an interpretative network system to which both the creator and the consumer of the texts refer. One of the functions of codes is to simplify things with the view of facilitating the communication of ideas. The challenge is that of containing the multiplicity of meanings that a text could generate. This challenge is met by reading the signs of the text in accordance to what we deem as the more plausible codes. While textual codes do not ultimately establish the possible interpretations of texts, the prevailing codes limit them. Social practices function to curtail the meanings that an interpreter seeks to attribute to signs. Codes operate to ensure a 'preferred reading' as opposed to an 'aberrant decoding.' They are not limited to being instruments of communication; if anything they constitute systems of process belonging to related conventions that

function in specific contexts. Under the rubric of textual codes we find scientific codes (including mathematics), aesthetic codes (including the many expressive arts), genre, rhetorical, and stylistic codes, and mass media codes. Under the heading of social codes we find language, corporeal codes, commodity codes, and behavioral codes. The interpretative codes include perceptual codes and ideological codes. These three categories of codification are in their most important features linked to the triad of knowing that the interpreter of a text must possess; namely, (1) the world (social knowledge), (2) the medium and the genre (textual knowledge), and (3) the relationship between (1) and (2) (modality judgments). An example of a textual code is the *genre*. The first observation to be made is that any taxonomy of genres could never fully represent the multiplicity of elements and structures that are contained in texts. Any understanding of what constitutes a genre is the result of a negotiated consensus about the general and specific features of the given cultural product (Chandler, 2002: 159–160).

According to Petöfi, "textuality is not an inherent property of certain objects, but is rather a property assigned by those producing or analyzing them" (1986: 1080). Given this, Winifred Nöth (1995: 332) observes that the definitions of what constitutes a text are potentially numerous, namely, (1) In a much wider sense, texts as cultural messages of any code. From this vantage point, semioticians analyze a great array of cultural phenomena as texts (cinema, music, ceremonies, and so on), and (2) In a more restricted sense, texts as verbal messages. There are subsets of this definition: (a) text or discourse, here the verbal signs that are being studied are either oral or written. Beneviste employed *discourse* when referring to written and oral messages. German semioticians instead used the idea of the text; as well there is the tradition of discourse analysis. (b) text vs. oral discourse. Barthes limits the idea of text solely to written messages. (c) text vs. empirical discourse. In a way similar to the differentiation between *sentence* and *utterance* in linguistics, Teun A. Van Dijk characterizes text as the abstract structure embedded in discourse. (d) text vs. system. According to Louis Hjelmslev, text constitutes the semiotic aspect of process and syntagmatic relations, whereas system is defined as the chosen paradigmatic aspect and (e) text, utterance, enunciation. These elements refer to the text's pragmatic aspect. While enunciation is the specific act of speech production, the resulting act is utterance. Utterance can be defined as a presemiotic expression indicating the result of a speech act, namely, a text or simply a fragment of a text. Consequently, the text resulting from an enunciation includes traces of the speech act in the guise of indexical word items referring to the participants, time, and space of the enunciation (Nöth, 1995: 332).

From the pragmatic perspective, the text is understood as a vehicle of communication; it is the verbal message of an addresser meant for an addressee. This pragmatic view underscores the relationship between the text and its context, one consisting of textual and extratextual elements. Yuri Lotman, in this case, distinguishes between *expression* and *demarcation*. As expression, the text is constructed by means of the signs (*parole*) of the given system (*langue*). What is implied here is that the text is extraneous to the extratextual forms of *langue* that are not present in the text. Demarcation instead refers to the notion that the text is alien to the material signs of the context that are not part of the text. From the vantage point of its internal semantic and syntactic forms, the text is understood as an autonomous and to a limited extent a closed system. The individual signs are assimilated into an *integral sign*, thus creating the systematic unity of the text. According to Lotman, "a text is an integral sign and all the separate signs of the general linguistic text are reduced in the text to the level of elements of this sign" (1970: 22). In Greimas's semiotic theory of the text, the systematic wholeness of the text is explained within the context of *isotopy*.

The term *Textwissenschaften* (text class) is used in German and it concerns all those disciplines where texts play a major role; for example, literary studies, theology, law, history, psychology, philosophy, mathematics, logic, and others. *Textwissenschaften* focuses on analyzing texts that belong to different classes, but not only literary ones. There are three major premises underlying *Textwissenschaften*: (1) The *pragmatic* argument: if a specific role can be assigned to literary texts pragmatically and culturally, it would be erroneous to consider only texts of this type. Being a literary text is not an inherent category, it is instead a "context-dependent functional category which can be assigned to various texts" (Petöfi, 1986: 1086). (2) The *formal* argument: this deals with the macrostructures of texts. "Since very differently structured texts can be used to serve a literary function, no one-to-one mapping is possible between certain macrostructures and literary texts" (1086). (3) The *semantic* or *interpretation theoretical* argument: this refers to both how the interpretation approaches a text and how to assign the same text to different classes.

Hermeneutics is historically understood as one of the most ancient sciences of the text, and consequently it is a predecessor of any semiotic theory of texts (Nöth, 1995: 334). In fact, contemporary hermeneutics positions itself in a domain of inquiry that shares

many affinities with semiotics. The science of interpretation is rooted in philology, theology, and jurisprudence. The art of explaining, interpreting, and translating were central elements in Greek philosophy and mythology. In the *Epinomis* (975c) Plato makes reference to interpretation when discussing divination, which, together with interpretation, can be classified as a hermeneutic art (334). However, although both deal with the uncovering of meaning, divination discovers meanings in things that appear to not have any, while interpretation makes manifest meanings that exist beyond the principal meanings of the text in question. The defining methodological feature of classical text criticism was the focusing on essentially two levels of interpretation: (1) the surface level of the text, where the intent is to clarify the meaning of sentences and words; and (2) the deep level of the text, where the objective is to explain its hidden meanings. This approach was to eventually acquire the designation of allegory. The classical idea of two levels of interpretation gradually gave rise to a multilevel approach employed in Biblical interpretation. Challenged by the difficulty of being lodged between dogmatic readings and the possibility of uncovering new interpretations in the Bible, the Patristic authors cultivated an interpretative mode that has features of a theory of textual codes (Eco, 1984: 147–153).

There are three levels of scriptural exegesis: (1) the letter, where the focus is the grammatical construction; (2) the *sensus*, the meaning that was derived from the narrative context; and (3) the *sententia;* this is the more profound meaning of the text. The letter and the *sensus* constitute the cortex or surface structure. Moreover, the *sensus* is the first stage of the scriptural meanings (literal or historical sense). *Sententia* is the nucleus or deep structure and it envelops the three spiritual senses of the scriptural meanings (tropology or moral, allegory, and anagogy). The tropological level of interpretation refers to the meaning that the Bible has for the earthly life of a person. The allegorical level of meaning concerns the life of Christ and the Church. The anagogical level of meaning deals with the celestial mysteries whose significance will be unfolded in the future. To illustrate this multifold interpretation of the text we need only consider the reading of the Biblical account of Exodus offered by Dante in the 'Epistle to Cangrande.' Historically or literally, the story refers to the Israelites exiting from Egypt during the times of Moses. From an allegorical point of view, we are dealing with Christ's redemption of humankind. The moral (tropological) meaning is the soul's conversion from a state of sin to one of grace. Analogically, the story refers to the soul's movement from the enslavement under terrestrial corruptibility to eternal freedom.

As far as modern hermeneutics is concerned, the interpretation of texts can be achieved with neither induction nor deduction. Instead, textual understanding becomes possible by means of an interpretative model that is characterized by features similar to abduction. That is, the process of explaining things in accordance with assumptions and hypotheses concerning laws that are plausible but unproven. The criteria for establishing a correct interpretation of a text is based on the notion of textual monosemy, where the most relevant element is authorial intent. However, opposed to this is the assumption of textual polysemy, where the emphasis is on the reader's response. Eric D. Hirsch, who is a proponent of textual monosemy, distinguishes between meaning and significance: "*Meaning* is that which is represented by a text; it is what the author meant by his use of a particular sign sequence; it is what the sign represents. *Significance*, on the other hand, names a relationship between that meaning and a person, or a conception, or a situation, or indeed anything imaginable" (Hirsch, 1967: 8). Hans George Gadamer was instead more apt to recognize the role of textual polysemy (a concept that is not inconsistent with Barthes' *semiotropy*, Eco's *open text*, and Kristeva's textual polyphony). In Gadamer's mind, "Not only occasionally, but always, does the sense of the text surpass its own author. Therefore understanding is not mere reproduction but always a productive behavior [...] Understanding is in reality not better understanding [...] It suffices to say that one understands differently, if one understands at all" (cited in Nöth, 1995: 337).

Contemporary semiotic theories of the text are greatly indebted to the research undertaken in various East European centers, and which spawned movements such as Russian Formalism and the Prague Structuralists. Russian Formalism was rooted in two centers, the Petrograd Society for the Study of Poetic Language (Opoyaz), from 1916 to 1930, and the Moscow Linguistic Circle from 1915 to 1921. According to the testimony of Yuri Tynianov and Roman Jakobson, Saussure played a major influential role in Russian Formalism, especially as far as concerns the contrastive interplay between the synchronic and the diachronic, the idea of system, and the concept of 'langue and parole' (Tynianov and Jakobson, 1971: 101–102) The objective was to cultivate a scientific approach to literary and artistic textuality. A central goal was that of establishing the properties of poetry and art as compared with everyday speech and objects. It was from this perspective that Jakobson developed the theory of 'literariness.'

From the vantage point of Russian Formalism, the production of the poetic text was analyzed as an independent process or system that was not to be reduced to its components. In a more focused sense, a strategy that was employed to transform a text into a work of art was that of *device* (*priem*). To be sure, the devices of poetry are central to the process of 'making strange' (*ostranenie*). The result of this process is a cognitive revitalization within the context of automatization, whereby we become familiar with all that which belongs to the experience of the quotidian. In this way the literary text develops as a fluid system by means of assimilating original elements and discarding its automatized components. The Russian Formalists were as interested in internal structural components of textuality as they were in the dimension of expressivity. In fact, Šklovsky underlined the difference separating the story (*fabula*) from the plot (*syuzhet*). While story constitutes the precomposition series of episodes, plot is the aesthetic metamorphosis of the story into a composite narratological series, but it is also the mode that allows the story to become 'strange' (Nöth, 1995: 307–308).

The two main centers of Soviet semiotics are Moscow and Tartu in Estonia. The researchers associated with Soviet semiotics worked in a field of textual inquiry that included language and literature as well as other forms of expression such as the nonlinguistic and audiovisual. As a result, Lotman, who founded the Tartu center, analyzes visual and performative arts as well as linguistic and literary expression. As far as poetological research is concerned, Soviet text semiotics deals with the semantization of the mode of communication, and thus stylistic and metrical elements are afforded a semantic rationale.

The Prague Linguistic Circle, which was formed in 1926, included figures such as Jan Mukařowsky (1892–1975), N. Trubetzkoy (1890–1938), and Roman Jakobson (1896–1982). In their inquiry related to the nature of textuality the Prague School Structuralists underscored the notion that language is not an isolated synchronic system of pure form. If anything, in the words of Mukařowsky, "[T]he basic notion of structuralist thought is that of the interplay of forces, agreeing with and opposing one another, and restoring a distributed equilibrium by a constantly repeated synthesis" (Mukařowsky, 1977: 79). The Prague School Linguists afford major importance to a functional approach to aesthetics and culture. The aesthetic dimension of textuality is born in a dialectical process of foregrounding or deautomatization in opposition to a background of norms and automatization. This notion is ever present in the social context of art. Mukařowsky, in 'Art as Semiotic fact' (1934), explains that the work of art is to be perceived as a sign structure consisting of, "1) a perceivable signifier, created by the artist, 2) a 'signification /= aesthetic object / registered in the collective consciousness, and 3) a relationship which refers to the total context of social phenomena" (in Matejka and Titunik, 1976: 6). The relationship between the internal and extralinguistic ambit of the semiosis of poetic texts was commented upon by Jakobson, according to whom "the concept of the content of poetry is unstable and temporally conditioned … the poetic function, *poeticity* is an element *sui generis*, one that cannot be mechanically reduced to other elements" (in Matejka and Titunik, 1976: 174).

In summary, a Structuralist approach to texts consists of: (1) the rule of immanence, whereby the investigation takes place within a system that is for the greater part forged from a synchronic optic, (2) the rule of pertinence, that is, what is studied are those elements that have a distinctive feature, (3) the rule of commutation, where the commutation test is applied with the objective of establishing systematic oppositions in minimal pairs, (4) the rule of compatibility, the rules that condition the combination of elements in texts, (5) the rule of integration, whereby the elementary units must be assimilated into the totality of the system, (6) the rule of diachronic change, historical change is discerned by means of a synchronic reading of the system, and (7) the rule of function, where the communicative and other functional characteristics of the system are studied (Nöth, 1995: 295–296).

Roland Barthes described the Structuralist approach as being grounded in the processes of segmentation and articulation, the exploration of the elements and of "the syntax of the arts and of discourse." This claim opened text structuralism to the accusation of being a positivist methodology. Barthes countered this critique by indicating that such an approach contained aspects of creativity: "structuralism is essentially *an activity of imitation*, which is also why there is, strictly speaking, no *technical* difference between structuralism as an intellectual activity, on the one hand, and literature in particular, art in general" (Barthes, 1964: 214–215). The privileging of the objectivist myth of structuralism brought about the "death of structuralism" (Nöth, 1995: 296). There are characteristics that distinguish structuralism from text semiotics: the latter privileges meanings and signs while the former focuses on the network of relations. However, according to Jonathan Culler, "In fact the two are inseparable, for in studying signs one must investigate the system of relations that enables meaning to be produced and,

reciprocally, one can only determine what are the pertinent relations among items by considering them as signs" (cited in Nöth, 1995: 297).

Russian Formalism and Prague Structuralism are seen as having played a direct role in the development of French semiotics of the text beginning in the mid-1960s. Paul Perron identifies two main directions of French semiotics: "The first, founded on the Sausserrean–Hjelmslevian legacy, best represented by the work done by Greimas, has become known as the 'Paris School' of semiotics. This school, which concentrates more on syntactic and semantic domains of the discipline, adopts an immanentist attitude to texts" (Perron, 1997: 5). The second direction "is represented by the large number of works that draw their inspiration from a radical questioning of the structural principles defining semiosis. Julia Kristeva and especially Roland Barthes were instrumental in this respect" (6).

In Greimas's research, the primary logical functions present in a text assume a meaning. The actants, or agents, are characterized not by what or who they are but by how they operate and by their involvement in a variety of categorizable domains of action. Greimas's three-pronged point of reference for this sort of analysis consists of communication, desire, and text. The actants are distributed in a dualistic fashion. Moreover, the great quantity of personages in a narrative account is transformed into a signifying system, consisting of Subject/Object, Addresser/Addressee, Helper/Opponent, which becomes the underpinning for the narrative. Narrative in Greimas's mind, precisely because it is a mode of communication, relies on the existence of an Addresser (narrator) and Addressee (narratee). The signifying traces of the Addresser and Addressee are perceived as being an important component of the text. Greimas explored a semantic theory of the text which he called 'generative trajectory.' The objective of this theory is to document the generation of discourses of any signifying system. Greimas identifies a triad of 'autonomous general areas' of interpretation: (1) semionarrative structures, (2) discursive structures, and (3) textual structures. Textual structures rest outside of the generative trajectory because they are foremostly structures of expression rather than of content. The generative trajectory represents discourse production as a system that evolves in different phases, each one possessing syntactic and semantic subcomponents. In other research projects Greimas studied the notion of building a discursive syntax rooted in aspectualities (states of a temporal process – inchoateness, duration, termination – that permit us to envision temporality as a signifying system).

Barthes played an important role in the promotion of the idea of 'text,' one of his most prominent writings about it being 'De l'oeuvre au text' (in *The Rustle of Language*). Barthes posits the advancement of the concept of the text in the context of interdisciplinary dialogues, that is, at once as the result of this encounter and as a reaction to interdisciplinarity. Moreover, for Barthes what is at issue here is not a deep-rooted change but "an epistemological slippage more than a veritable break" (Barthes, 1989: 56). In Barthes' mind, the text and the work are two opposing entities. However, the idea of the text does not substitute or supplant the idea of the work. Instead, the text is something previously unthought and unseen. The text's characteristic is "its force of subversion with regard to the old classifications." Moreover, the text is "what is situated at the limits of the rules of speech act (rationality, readability, etc.)" (Barthes, 1989: 58). Barthes makes a distinction between 'work' and 'text': the work is something that can be located and described, while the text cannot be located nor be counted. All works contain some presence of text; however, the pure text is something that resists locatable presence and analysis. According to Barthes, "we must not permit ourselves to say: the work is classical, the text is avant-garde." The reason for this is that "there can be some text in a very old work, and many products of contemporary literature are not works at all" (Barthes, 1989: 57).

In another writing, 'Young Researchers,' Barthes explains that when we talk about the idea of the *Text* "it is not in order to make it divine, to make it the deity of a new mystique, not to denote a mass, a field requiring a partitive and not a numerative expression: all that can be said of a work is that there is a Text in it" (Barthes, 1989: 73). The implication of Barthes' opposition between work and text is that while a work such as, say, Dante's *Divine Comedy* can be studied as a "product of an authorial intention, with a meaning that had to be sought, and aesthetic unity to be valued," it can also be read as a text, as a product "of sign systems and of intertextuality, instances of intermediate functioning of language, part of historical processes of production and reception" (Culler, 2001: 443).

In essence, when discussing Barthes' concept of the text we need to keep in mind the distinction he makes between "semiology . . . as the positive science of signs" and what he terms "my semiology." For Barthes, language constitutes an oppressive set of rules, literary production is an act of rebellion against language, while semiotics is a creative activity: "Semiology . . . does not rest on a 'semiophysis' . . . and it is also not a 'semioclastry,' [. . .] Rather . . . it is a 'semiotropy' turned toward the sign, this semiology

is captivated by and receives the sign, treats and if need be, imitates it as an imaginary spectacle. The semiologist is, in short, an artist" (cited in Nöth, 1995: 313).

The relevance of Julia Kristeva's research on the concept of the text is generated by means of a new science she calls "semanalysis." Her project came about as a reaction against the fact that, in her own words, "our philosophies of Language, embodiments of the Idea, are nothing more than the thoughts of archivists, archaeologists, and necrophiliacs" (Kristeva, 1984: 13). Against this, and through semanalysis (a combination of semiotics and psychoanalysis), Kristeva seeks to direct the return of the speaking body, replete with its drives and impulses, into language. Kristeva achieves this goal by claiming that the strategies of signification are latent in the body, and by arguing that corporeal impulses are present in language.

An influential concept put forward by Kristeva is the distinction between the semiotic and the symbolic. The semiotic entities, which Kristeva differentiates from 'semiotics,' within the context of sign systems, constitute the bodily impulses as they are made manifest in language, more specifically as features of rhythm and tonality. However, what we would term 'semiotic' is the hidden dimension of meaning within signification which is bereft of the ability to signify. The symbolic, however, is the dimension of signification that does signify, and it is linked to syntactical and grammatical elements. In Kristeva's semanalytic project, the concept of the text plays a pivotal role. Kristeva characterizes the text as "a translinguistic apparatus that redistributes the order of language, relating a communicative 'parole' aiming at direct information to different types of previous synchronic utterances. The text is thus productivity, which means: 1) Its relation to the language in which it is situated is redistributed (destructivo-constructive) . . . 2) It is a permutation of texts, an intertextuality" (Kristeva, 1969: 113).

For Kristeva, language systems and text are diametrically opposed, and where the latter operates as that element which undoes the system: "Submerged in language, the 'text' is consequently . . . that which changes it, which dissolves it from the automatism of its habitual development . . . . The (poetic, literary or other) 'text' digs into the surface of speech a vertical shaft where the models of that significance are sought which the representative and communicative language does not recite even if it indicates them." To the notion of the text immersed in the signifying properties of language, Kristeva adds that the "text is not the communicative language codified by grammar. It is not satisfied with representing or meaning the real. Wherever it signifies . . . it participates in the transformation of reality, capturing it at the moment of nonclosure" (Kristeva, 1969: 8–9).

'Intertextuality' (Latin *intertexto*, 'to intermingle while weaving') is a term used extensively by Kristeva. In 'Word, dialogue, and novel,' for example, Kristeva discarded the traditional concepts of the author's 'influences' and the text's 'sources,' and claimed that all signifying systems are structured in accordance to the way they alter previous signifying systems. Consequently, a literary work is more than the result of a single author's efforts. If anything it is the result of the text's relationship to other texts and to the components of language itself. "[A]ny text," Kristeva tells us, "is constructed of a mosaic of quotations; any text is the absorption and transformation of another" (Kristeva, 1980: 66). In this way, intertextuality constitutes a manner of explaining the role of literary and extraliterary elements without needing to make reference to traditional concepts such as authorship. The notion of intertextuality weakens the idea of the text as self-sufficient entity, and reinforces, instead, the fact that all textual production occurs in the presence of other texts. All texts are, in essence, a seemingly infinite series of connected palimpsests. In Barthes' mind intertexuality permits the text to come into presence, precisely because a text is a "new tissue of past citations." By this Barthes implies that the text is constituted by "[b]its of code, formulae, rhythmic models, fragments of social languages" and so on, all of which "pass into the text and are redistributed within it, for there is always language before and around the text." Barthes reiterates a notion that is key to conflicts with traditional notions of textual authority when he explains that "[i]ntertextuality, the condition of any text whatsoever, cannot, of course, be reduced to a problem of sources or influences; the intertext is a general field of anonymous formulae whose origin can scarcely ever be located; of unconscious or automatic quotations, given without quotation marks" (Barthes, 1981: 39). However, intertexts are not limited to being only 'literary' in that historical and social factors constitute signifying practices that alter and shape literary practices. A text comes into being in the event of its reading. Consequently, the reader's own previous readings, experiences, and place within the cultural environment constitute important intertexts as well. The idea of intertextuality weakens the boundaries of the text, by subverting unity and assimilation and replacing it with a limitless texture of connections, associations, paraphrases, fragments, texts, and contexts.

Gerard Genette elaborated the notion of 'transtextuality' as a more global term than 'intertextuality' (Genette, 1997b). Genette established the outlines of

the notion of transtextuality in *The architext: an introduction,* where he writes that "for the moment the text interests me (only) in its *textual transcendence* – namely, everything that brings it into relation (manifest or hidden) with other texts. I call that *transtextuality*" (Genette, 1992: 81). However, transtextuality is not synonymous with intertextuality, which is part of a textual typology that includes five elements:

Intertextuality This is qualified as "the literal presence (more or less literal whether integral or not) of one text within another" (Genette, 1992: 11). Quoting other texts is an overt intertextual relation, but allusion and plagiarism as well belong to the purview of Genette's definition. David Olson (1991) qualifies text as the cultural object that is the subject of commentary, which constitutes an object of discussion or dialogue; in other terms, the cultural artifact that can be quoted. In the case of the Tartu school, texts function to choose what is to be remembered or forgotten, thus creating a value basis for defining text.

Paratextuality This pertains to the connection linking a text and its 'paratext' – that which surrounds the main body of the text – such as titles, headings, prefaces, epigraphs, dedications, acknowledgments, footnotes, illustrations, dust jackets, and so on; namely, "those liminal devices and conventions, both within the book (peritext) and outside it (epitext), that mediate the book to the reader" (Genette, 1997b: 10). As suggested by the subtitle of Genette's study on paratexts, *Thresholds of interpretation*, paratexts are found at the extreme limits of a text, thus constituting a "zone without any hard and fast boundary on either the inward side (turned toward the text) or the outward side (turned toward the world's discourse about the text)" (Genette, 1997a: 2). The paratext lies between the text and the *hors-texts*, "all the ways in which a text makes itself a book and presents itself as such to its readers, and more generally to the public" (7).

Architextuality This refers to the designation of a text as part of a genre or genres. An *architextual* relation is the one that "links each text to the various types of discourse it belongs to. Here we have the genres, with their determinations that we've already glimpsed: thematic, formal, modal and other" (Genette, 1997a: 2).

Metatextuality This designates an explicit or implicit critical commentary of one text on another text. Genette describes metatext as "the transtextual relation that links the commentary to the text it comments upon. All literary critics, for centuries, have been producing metatexts without knowing it" (Genette, 1997a: 82). We can say that metatext refers in good part to secondary texts that comment upon a text or place it within a larger context. This would include comments, reviews, catalogues, classifications, journals, tables of contents, subject indexes, bibliographies, and so on. Admittedly this category spans from critical texts (comments, reviews), over classificatory texts, to purely arbitrary catalogues.

Hypotextuality (Genette employs the term *hypertextuality.*) This concerns the link between a text and a previous 'hypotext' – a text or genre on which it is based but which it metamorphizes, alters, elaborates, or extends (this involves forms such as parody, spoof, sequel, and translation). *Hypotextual* relations are characterized in a manner that is different from computer-related qualifications. They are constituted by "relationships of imitation and transformation, which pastiche and parody can give us an idea of" (Genette, 1997a: 67). But the overlapping of texts upon texts is to be conceived in a metaphoric or semantic sense.

Intertextuality and paratextuality can be characterized by means of models originating from textual forms qualified by their link to primary texts (that is, titles, references). Metatextuality and hypotextuality are instead to be conceived in connection to more abstract cases of links with primary texts. With an even greater degree of abstraction, architextuality designates the thematic and stylistic characteristics of a text, thus locating it within the larger corpus of texts. What is key here is the idea of 'threshold': this refers to a second-order textuality, functioning at a level that is different from the one in which texts-as-works operate. To be sure, a significant number of texts qualified as being second-order textuality are secondary text. Here 'secondary' refers to the fact that they form a domain of semantic relations 'around,' 'about,' and 'in-between' scholarly texts. Secondary texts assume their currency in virtue of a primary text.

'Hypertext' refers to the structuring of information as a linked network of nodes that allows the reader to navigate in following a direction that is nonlinear. Moreover, hypertext makes it possible for there to be more than one author, a blurring of the author and reader functions, extended works with diffuse boundaries, and multiple reading paths. The term 'hypertext' was originally coined to express the idea of 'nonsequential writing.' But subsequently writers have taken hypertext to be a distinctly electronic technology – one that must involve a computer; that

is, hypertext, as a DBMS that allows one to connect screens of information using associative links. Hypertext is ultimately a software environment setting for cooperative work, communication, and knowledge acquisition. Hypertext software imitates the neurological operations of storing and retrieving data by means of links for immediate access. Hypertext is not, in the end, the exclusive domain of technology. To be sure, hypertext is an organizational paradigm that functions within both a chartaceous and electronic environment.

Umberto Eco has played a major role in elaborating a notion of text that has been highly influential in contemporary semiotic practices. In *Interpretation and overinterpretation,* Eco makes an assertion concerning the signifying nature of texts that sheds important light on his own textological philosophy. In Eco's mind a text constitutes "a device conceived in order to produce its model reader .... A text can foresee a model reader entitled to try infinite conjectures (Eco, 1992: 64). In other terms, Eco affords to the text a signifying autonomy that is to be understood, however, within the context of a larger semiotic web that involves a dialectic relationship between text, author, interpreter, and, in the most general terms, the exterior world of signs. Eco clearly privileges the ontological status of the text when he informs his reader that "[t]o recognize the *intention operis* is to recognize a semiotic strategy. Sometimes a semiotic strategy is detectable on the grounds of established stylistic conventions" (Eco, 1992: 64–65). Eco is essentially reformulating what he had previously written in *The role of the reader*, namely, in each text there is implicit an author who devises a work and who constructs its semiotic strategies: "[I]n the dialectics between the intention of the reader and the intention of the text, the intention of the empirical author has been totally disregarded .... We have to respect the text, not the author as person so-and-so. Nevertheless, it can look rather crude to eliminate the poor author as something irrelevant for the story of an interpretation" (Eco, 1992: 65–66).

It would be fair to say that since *The open work* (Italian edition 1962, English edition 1989), Eco has been concerned with "the dialectics between the rights of texts and the rights of their interpreters" (Eco, 1992: 59). In Eco's view an imbalance has been created in this dialectical relationship with the rights of the interpreter receiving undue privilege, or what he terms 'overinterpretation.' The root of Eco's critique of overinterpretation is explained through the Peircean concept of unlimited semiosis, which Eco elaborates at length. Eco stresses the idea that unlimited semiosis does not imply that textual interpretation is devoid of criteria: "[U]nlimited interpretation concerns systems not processes. A linguistic system is a device which, and by using which, infinite linguistic strings can be produced. If we look at a dictionary for the meaning of a term we find definitions and synonyms, that is, other words, and we can go to see what these words mean, so that from their definition we can switch to other words and so on potentially *ad infinitum*" (Eco, 1997: 59). However, as Eco tells us, texts as the artifact produced by means of what he calls the "manipulation of the possibilities of a system", are not open in a similar manner. Eco's argument is that in the act of creating a text with signifying structures, one necessarily limits the extent to which the linguistics elements can be used. In other terms, "by reducing the possibility of producing infinite strings, a text also reduces the possibility of trying certain interpretations." If a text can withstand a vast number of interpretations, that is not to say that "interpretation has no object." Eco offers a criterion of falsification, inspired by Popper, according to which "if it is difficult to decide if a given interpretation is a good one, and which one is better between two different interpretations of the same text, it is always possible to recognize when a given interpretation is blatantly wrong, crazy, far fetched." Eco articulates the difference between the intentions of each of the author, reader, and text by indicating that given that the text is an instrument whose goal it is to invent the Model Reader, "This Reader is not the one who makes the 'only/right' conjecture. A text can foresee a Model Reader entitled to try infinite conjectures." The basis for establishing a conjecture about the text's intention is that "any interpretation given of a certain portion of a text can be accepted if it is confirmed and must be rejected if it is challenged by another portion of the same text. In this sense the internal textual coherence controls the otherwise uncontrollable drives of the reader" (Eco, 1997: 60).

If the text is produced for a community of readers, the author will unquestionably be aware of the fact that he or she will not be read in congruency with his or her intentions, but rather in accordance with what Eco calls the "social treasury" of the community of readers. By 'social treasury,' Eco implies not solely a specific language as a series of grammatical rules "but also the whole encyclopedia that the performances of the language have implemented, namely, the cultural conventions that the language had produced and the very history of the previous interpretations of many texts, comprehending the text that the reader is in the course of reading" (Eco, 1997: 60).

For Eco the Model and the Empirical Reader are not one and the same: "The empirical reader is you and me, when we read a text. Empirical readers can

read in many ways, and there is no law which tells them how to read, because they often use the text as a container for their own passions, which may come from outside the text, or which the text may arouse by chance" (Eco, 1997: 61). In *Six walks in the fictional woods* Eco suggests that the Model Author is a voice which reveals itself as a "narrative strategy, as a set of instructions which is given to us step by step and which we have to follow when we decide to act as the model reader" (Eco, 1994: 15).

Deconstruction brought about a radical rethinking of text and textuality and it was initiated by Jacques Derrida in a number of writings published from the late 1960s onward. Derrida's concept of deconstruction promoted a particular mode of interpreting a wide disciplinary range of texts that stressed the logical or rhetorical incongruencies between a text and its meanings. For example, the deconstructive turn sought to illustrate, by focusing on the binary operations inscribed in a text, how the oppositions are composed from a hierarchical perspective. However, the hierarchical structure is turned upside down, thus allowing the text to say the contrary of what it had stated in the first place. Finally, the two elements of the opposition are placed within a context of difference where all hierarchical categorizations are abolished.

Deconstruction is in great part synonymous with poststructuralism. The three major sources of the movement are Friedrich Nietzsche, Martin Heidegger, and Ferdinand de Saussure. In the *Course in general linguistics* (1916) Saussure created the foundation for structuralism by documenting concepts such as (1) the arbitrary nature of the linguistic sign, (2) the partitioning of the sign into signifier and signified, and (3) the idea that language is rooted not so much in nomenclature and correspondence as it is in 'difference.' As a consequence, the arbitrary nature of the sign implies the lack of an intrinsic, fundamental basis for signifying a specific idea through a specific word. Thus, the meaning of a word is essentially arbitrary although the meaning is the result of convention and use.

A deconstructive theory of the text pivots on the idea that textuality is the repository of binary oppositions (signifier/signified, presence/absence, literal/figural), of segments of reasoning, of words that are all informed by radical rhetorical and logical incoherencies that cannot be assimilated into a textual harmony or unity. These signifying incompatibilities reveal to the text itself the characteristics of its own difference. That which the text communicates and how it communicates it are estranged from each other. This Derridean view of the textuality can be summed up in Barthes' words, when he suggests that the text is "a tissue of signs, an imitation that is lost, infinitely deferred" (Barthes, 1977: 147).

For Derrida, speech has traditionally been privileged over writing thus leading to the logocentric bias of Western culture. Derrida subsumed the notion of linguistic difference theorized by Saussure and coined the term 'différance.' This term conserves Saussure's idea of noncoincidence and points to the notion of spatial and temporal differing. However, Derrida includes the entire domain of signs under the rubric of 'différance.' Moreover, he refers to this domain as *écriture* (writing), that is, not in the conventional terms of graphic script, but rather in the metaphorical sense of writing as a signifying process or system that contains 'différance.' 'Grammatology' is the science of writing and it entails the study of the relations between terms within a bound signifying system where each of the elements assumes semiotic currency on the basis of its opposition to other elements. This being the case, a text, precisely because it is a signifying system whose textuality is molded by 'différance,' is problematic in that it brings to the fore questions about referentiality and meaning. Derrida concludes that there exists nothing 'outside' the text; moreover, signification is structured from within the semiotic system as an operation of difference. In this way, textual reference is transformed into self-reference. The representation communicated by textuality, according to the logic of deconstruction, is not so much a mimetic performance of the world as it is self-representation, whereby signifying processes hide and unhide themselves thus producing an empty mask of referentiality that cloaks an abyss of linguistic signs. Deconstruction has promoted the rethinking of language and the world from the perspective of textuality, and it is for this reason that it has played a key role in directing the theoretical thinking found in a wide range of disciplines, cultural studies in particular.

What has been said so far has been from within the context of verbal texts. However, the discussion is indeed also applicable to nonverbal texts such as, say, maps and other visual mediums of communications (cinema, television) as well as oral or social conventions of transmission and articulation of meanings. Within the context of cultural semiotics all that which 'belongs' to or which may be accounted for by a particular signifying system is deemed to be a text. Roland Posner (1989) has explained the extension of the notion of text from the vantage point of the written text to the one found in cultural semiotics by underlying three features: (1) the movement from writing to speech: that is, any sequence of words, not only recurring linguistic elements but also spontaneous ones, can be described as text, provided that the content is determined by a code; (2) the movement

from speech to any series of conventional signs: this goes beyond spoken and written signs to any sequence of coded signs whatsoever, such as traffic signs; and (3) the movement from a coded sequence to any coded sign, even if it has not become part of the sequence. Here, the text is essentially anything that could be reproduced. From the perspective of the Tartu school a 'cultural text' is the total aggregate of all the texts in a culture. The cultural text is heterogeneous when its components are ascribed to the linguistic system, the visual system, the behavioral system, and so on, but it is homogeneous when thought of in connection with the culture system.

According to Paul J. Thibault, the text-as-object is essentially a material entity, a cultural artifact that has been generated in and by means of a culturally definable social activity; the text is the result of the social semiotic process that generated it. But as a material product, text-as-object can only be an incomplete archive of the social activities that created it. In Thibault's own terms, "The (written) text is not a form of morse-code which simply stores and transmits preexisting meanings without also transforming them" (Thibault, 1994: 10). The point is that the written text can be characterized as a recontextualization from one signifying system to another. The material permanency of the text obscures the fact that it is a written transcript of an original speech act and in being so it is ultimately always a recontextualization of the signifying components that gave rise to the event (speech, paralanguage, kinesics, gestures, and so on), thus transposing them onto signifying modalities of the second (graphological) system. Along with the phenomenon of the text-as-object, Thibault identifies what he calls 'the semiotic action text,' which is fluid and processual, rather than synoptic and objectlike.

Finally, we have the phenomenon of the 'social text,' that is, a text that is somehow known and understood by a community of people, an overriding text that informs a society. Danesi (2000: 231) proposes as an example of this phenomenon the Christian social text, where we see that it is rooted in a worldview that is informed by the Bible and theological traditions. The Bible being, in the most traditional sense, by means of antonomasia, *the* text. It is for this reason that significant religious dates such as Christmas and Easter are annual events that are celebrated. In the case of Early Modern Europe the Christian text played an important role in structuring the daily activities and behavior of individuals and communities. Emphasis was placed on attending the celebration of Mass, acts of repentance and charity, and, in general, adhering to a code of moral conduct that was dictated by the Bible. The transcendent function characteristic of the Early Modern Christian social text was that of allowing the individual to understand the theological logic behind the idea that each moment of terrestrial existence gradually brought one closer to the event of what was perceived to be one's true destiny, namely, redemption and life after death in the presence of God. However, following the ages of the Renaissance, the Enlightenment, and the Industrial Revolution, the function that belonged to the Christian social text was appropriated by a form of textuality that separated religion from the state, thus creating a social text that was secular and immanent rather than theological and transcendent. In our current civilization the secular text is constituted by signifying systems and networks that create the context for, say, social and work commitments, but where the issue of salvation is compartmentalized in specific and limited domains of daily life. It is only on the occasion of a restricted number of calendar dates, in particular, Christmas and Easter, that the secular text coincides with the traditional theological text.

Thailand: Language Situation

S Premsrirat, Mahidol University, Phutthamonthol Nakhonpathom, Thailand

© 2006 Elsevier Ltd. All rights reserved.

Multilingualism in Thailand

Located at the heart of Southeast Asia with its 60 million people speaking more than 70 languages, Thailand represents a complex situation of language diversity, the definitive characteristic of the region. Standard Thai, based on a variety of Central Thai, the only official and national language, is used as the medium of instruction in schools and the mass media. The Thai writing system is based on an Indic alphabet originally designed for Sanskrit. Influential languages that have influenced the development of Standard Thai include Pali, Sanskrit, Khmer, Chinese, and English. Other languages of Thailand remain regional or local (minority) languages.

Genetic Classification and Distribution

Languages in Thailand belong to five language families: Tai-Kadai, Austroasiatic, Austronesian, Sino-Tibetan, and Hmong-Mien.

Multilingualism in Thailand

Located at the heart of Southeast Asia with its 60 million people speaking more than 70 languages, Thailand represents a complex situation of language diversity, the definitive characteristic of the region. Standard Thai, based on a variety of Central Thai, the only official and national language, is used as the medium of instruction in schools and the mass media. The Thai writing system is based on an Indic alphabet originally designed for Sanskrit. Influential languages that have influenced the development of Standard Thai include Pali, Sanskrit, Khmer, Chinese, and English. Other languages of Thailand remain regional or local (minority) languages.

Genetic Classification and Distribution

Languages in Thailand belong to five language families: Tai-Kadai, Austroasiatic, Austronesian, Sino-Tibetan, and Hmong-Mien.

Tai-Kadai The majority or 92% of the population speak Tai languages. There are 24 Tai languages or dialects distributed all over the country, which are listed below:

Tai languages of Thailand

Kaloeng	Khammuang (Northern Thai) (Yuan)	Lao Khrang
Lao Isan (Northeastern Thai)	Lao Lom	Lao Ngaew
Lao Tay	Lao Ti	Lao Wiang (Lao Klang)
Nyoh	Phuan	Phu Thai
Paktay (Southern Thai)	Seak	Tai Dam (Song)
Tai Lue	Tai Ya	Tai Yai (Shan)
Thai Klang (Central Thai)	Thai Korat	Thai Loei
Thai Takbai	Yong	Yoy

Austroasiatic The more numerous and smaller language groups that are scattered throughout the country are Austroasiatic languages. These are the indigenous languages of Southeast Asia. They comprise 4.3% of Thailand's population. There are 23 major languages, as indicated below:

Austroasiatic languages of Thailand

Bru, western	Chong	Dala-ang (Palaung)
Kasong	Kensiw	Kuy
Khmu	Lamet	Lavue
Mal-Pray (T'in)	Mlabri	Mon
Nyah Kur	Nyeu	Plang
Samre	Sa-oc (Chung)	So (Thavueng)
Vietnamese	Wa	

Sino-Tibetan The Sino-Tibetan languages include seven Chinese dialects found mainly in the towns of the country, except Haw (Yunnanese Chinese), which is spoken by people who settled in the border area in the north; and 14 Tibeto-Burman languages whose speakers are concentrated mainly in the north and northwest of Thailand. Speakers of Sino-Tibetan languages comprise 3.1% of the population.2

Sino-Tibetan languages of Thailand

Chinese dialects:	Tibeto-Burman Languages:	
Cantonese	Akha	Bisu
Hainan	Burmese	Bwe
Hakka	Gong	Jingpo (Kachin)
Hokkien	Kayah, eastern	Kayo
Haw (Yunnanese)	Lahu	Lisu
Mandarin	Mpi	Padong
Teochiu	Pagayaw (Sagaw Karen)	
	Pwo (Pow Karen)	

Hmong-Mien Speakers of the Hmong-Mien or Meo-Yao languages are concentrated mainly in the north of Thailand. They comprise 0.3% of the population. There are two major languages, i.e., Hmong (Black and White) and Mien.

Austronesian The Austronesian speakers are found mainly in southern Thailand. They comprise 0.3% of the total population. There are three major languages, i.e., Malay, Moklen, and Urak Lawoi.

Language Hierarchy and Diglossia

Languages in Thailand are socially related in a hierarchical way (Smalley, 1988, 1994). Each language belongs to a different level and has a role and function in the society.

National Language Standard Thai is the national and official language of the country. It is used as the medium of instruction in schools, the mass media, and on all formal occasions throughout the country.

Regional Languages The four major regional Thai languages are Northern Thai or Kammuang, Northeastern Thai or Lao Isan, Southern Thai or Paktay, and Central Thai or Thai Klang. Each of these is a vernacular language in a local community, as well as a lingua franca among the minority languages in the region.

Local Languages Languages spoken in the local communities are mainly minority languages, which are classified into four groups.

1. Displaced languages are languages that are historically associated with people who have moved from their original homeland to settle in Thailand because of wars, famine, and work opportunities. For some of these migrants, their ancestors were prisoners of war coming from neighboring countries in the early years of the Rattanakosin period (from 1782 onward). The majority of the displaced languages are Tai, for example, Phuan, Song, Phuthai, Lao Wiang, Lao Khrang, Nyoh, Yooy, Kaloeng, etc. Non-Tai languages include Mon and Khmu in central Thailand.
2. Town languages are Chinese and Vietnamese (upper northeastern region).
3. Marginal languages are found near the borders, with the majority of speakers living on the other side of the border. They are languages such as Shan and Khmu in the north, Khmer in the

northeast, Mon (Burmese Mon) in the northwest, and Malay in the south. These languages are spoken across the countries in Southeast Asia

4. Enclave languages are languages spoken by small isolated ethnolinguistic groups who live in the area surrounded by totally unrelated languages and are wholly contained in the country. There is no means to communicate with relatives who live outside these communities. Some are the descendants of people who lived in ancient empires, such as the Nyah Kur who settled in the center of Thailand, and the Chong, Kasong, and Samre in the east near the Cambodian border. Others are the So (Thavueng) on the upper Korat plateau, Gong in the central plain, Lavue, Mlabri, Bisu, and Mpi in the north, and Urak Lawoi and Moklen in the south.

Thai nationals, especially the ethnolinguistic minorities, are bilingual or multilingual. They speak their ethnic language at home with family members and neighbors in the same community and also speak a regional or national language outside their community, depending on the social domain and the people they are speaking to. In schools and government offices, on formal occasions, and in the mass media, Standard Thai is used. However, this diglossic situation is now decreasing, as Thai is being spoken in more and more social settings in the lives of ethnic minorities.

Language Policy, Language Shift, and Language Maintenance

The national language policy is to promote only Standard Thai at all levels of education and in the mass media, including modern economic development, new urban cultures. As a result, the powerful mass media have been playing a vital role in the destruction of indigenous languages and cultures in Thailand. Ethnic minority languages are declining at different rates. Even the major regional Thai languages show signs of contraction, especially in the loss of vocabulary and aspects of grammar, whereas some small languages have been replaced by Thai and have ceased to be the language of the speech community or even the home. Currently, at least 14 languages in Thailand face imminent endangerment: Chong, Kasong, Samre, Sa-oc, Lavua, Nyah Kur, Thavueng, Mlabri, Kensiw, Mpi, Bisu, Gong, Urak Lawoi, and Moken/Moklen (Suwilai, 2001). However, there is a movement to provide a foundation for preservation against the dominant Thai language. The use of the Lanna (Kammuang) writing system has been revitalized and is now taught in some schools. Thai-based orthographies for some ethnic minority languages have been developed for unwritten languages, such as Chong, Nyah Kur, Thavueng, and Gong, so that their speakers can use these orthographies to record their language, in order to slow down the shift to Thai, and to teach the languages to the younger generation as a part of the revitalization and maintenance programs.

.

Studies of John Thelwall's manifold output are beginning to assume significant proportions. The pioneering analyses of his political and literary roles (Thompson, 1963, 1997) have been succeeded by appraisals of his speech theory and practice (Rockey, 1980; Thelwall, 1981) and more recent work on his literary role *vis-á-vis* Wordsworth and Coleridge (Thompson, 2001).

Born in London, the son of a silk mercer, he suffered from a lisp and weak lungs and received elocution lessons from a clergyman, Harvey. He aspired to a literary career, but was forced to take up the law

briefly to support his widowed mother. His literary contacts brought him into contact with Henry Cline, anatomy professor at St Thomas' Hospital, whose lectures he attended. His anatomical awareness, combined with his rhetorical interests (which in this period covered much of both normative and pathological intervention), led to his later successful career as an elocutionist between 1803 and 1826. His primary passion in the early 1790s was politics. He was a founding member of the London Corresponding Society – a radical organ of the politically aware urban artisan class. The chief ideas of the radicals of that time being heavily influenced by French Jacobinism, it is not surprising that the British government of the day felt threatened and charged a number of radicals, including Tooke and Thelwall, with treason, though they were, somewhat to their surprise, subsequently acquitted.

Thelwall had also come into contact with Wordsworth and Coleridge through their youthful radicalism. After his release from Newgate prison he wandered the countryside, giving speeches in various parts of the country. He went to visit the Wordsworths in Somerset and was pursued by government spies. He finally sought refuge as a hill farmer in central Wales with his wife and brother-in-law. This experiment soon failed. A wish to pursue his real interest in literature combined with his rhetorical skills, part of his radical political appeal, proved serviceable on the public lecture circuit. He embraced the new patriotism and performed for mass audiences all over England. During these lectures he dealt with several cases of speech impediments and realized there was a living in this. After a short period running an institute in Liverpool he moved to London, where he opened one in Grays Inn Fields, London. He provided plays done by his pupils that were open to the public. These soirees were attended by fashionable London, including Charles Lamb and De Quincy.

In the late 1820s he returned to radical journalism as an editor and financier. This was a disastrous failure. After his death, his second wife published the first volume of a projected two-volume biography. A second volume was to have covered his elocutionary life.

His contribution to the study of the English language and therapeutic elocution rests on his advanced understanding of anatomy, his skill in diagnosing and intervening in speech disorders, including the original (paralleling Steele, whom he did not read till later) analysis of stress-timed rhythm as underlying all spoken English. We have the bare bones of his knowledge in his *Letter to Henry Cline* and various sketches of his lecture notes.

Thematic Structure

S Wechsler, University of Texas, Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The **thematic structure** of a linguistic expression is a partial representation of its meaning, consisting minimally of a semantic relation and its arguments, often elaborated with more detailed semantic and syntactic information. For example, the verb *bake* in sentence (1a) expresses a **bake′** relation between two participants, the Baker (in this case, Jonas) and the product of the baking event or Bakee (in this case, the gingerbread). Using the standard logical notation in which **R** ($x_1, \ldots, x_n$) represents an n-place relation **R** with arguments $x_1, \ldots, x_n$, the thematic structure of (1a) is shown in (1b):

(1a) Jonas is baking the gingerbread.
(1b) **bake′** (*Jonas*, *the-gingerbread*)
(1c) **bake′** (Baker: *Jonas*, Bakee: *the-gingerbread*)

briefly to support his widowed mother. His literary contacts brought him into contact with Henry Cline, anatomy professor at St Thomas' Hospital, whose lectures he attended. His anatomical awareness, combined with his rhetorical interests (which in this period covered much of both normative and pathological intervention), led to his later successful career as an elocutionist between 1803 and 1826. His primary passion in the early 1790s was politics. He was a founding member of the London Corresponding Society – a radical organ of the politically aware urban artisan class. The chief ideas of the radicals of that time being heavily influenced by French Jacobinism, it is not surprising that the British government of the day felt threatened and charged a number of radicals, including Tooke and Thelwall, with treason, though they were, somewhat to their surprise, subsequently acquitted.

Thelwall had also come into contact with Wordsworth and Coleridge through their youthful radicalism. After his release from Newgate prison he wandered the countryside, giving speeches in various parts of the country. He went to visit the Wordsworths in Somerset and was pursued by government spies. He finally sought refuge as a hill farmer in central Wales with his wife and brother-in-law. This experiment soon failed. A wish to pursue his real interest in literature combined with his rhetorical skills, part of his radical political appeal, proved serviceable on the public lecture circuit. He embraced the new patriotism and performed for mass audiences all over England. During these lectures he dealt with several cases of speech impediments and realized there was a living in this. After a short period running an institute in Liverpool he moved to London, where he opened one in Grays Inn Fields, London. He provided plays done by his pupils that were open to the public. These soirees were attended by fashionable London, including Charles Lamb and De Quincy.

In the late 1820s he returned to radical journalism as an editor and financier. This was a disastrous failure. After his death, his second wife published the first volume of a projected two-volume biography. A second volume was to have covered his elocutionary life.

His contribution to the study of the English language and therapeutic elocution rests on his advanced understanding of anatomy, his skill in diagnosing and intervening in speech disorders, including the original (paralleling Steele, whom he did not read till later) analysis of stress-timed rhythm as underlying all spoken English. We have the bare bones of his knowledge in his *Letter to Henry Cline* and various sketches of his lecture notes.

Thematic Structure

S Wechsler, University of Texas, Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The **thematic structure** of a linguistic expression is a partial representation of its meaning, consisting minimally of a semantic relation and its arguments, often elaborated with more detailed semantic and syntactic information. For example, the verb *bake* in sentence (1a) expresses a **bake′** relation between two participants, the Baker (in this case, Jonas) and the product of the baking event or Bakee (in this case, the gingerbread). Using the standard logical notation in which **R** ($x_1, \ldots, x_n$) represents an n-place relation **R** with arguments $x_1, \ldots, x_n$, the thematic structure of (1a) is shown in (1b):

(1a) Jonas is baking the gingerbread.
(1b) **bake′** (*Jonas*, *the-gingerbread*)
(1c) **bake′** (Baker: *Jonas*, Bakee: *the-gingerbread*)

The argument positions can be given the explicit labels Baker and Bakee, as in (1c). This notation allows us to distinguish the different roles of the subjects in the intransitive (2a) and (2b):

(2a)	Jonas is baking.	**bake′** (Baker: *Jonas*)
(2b)	The gingerbread is baking.	**bake′** (Bakee: *the-gingerbread*)

The semantic roles played by the participants in the denoted event or state, such as Baker and Bakee, are called **thematic roles** or theta-roles (θ-roles). While (1) and (2) show the thematic structures of sentences, we may abstract away from the fillers of the roles and notate the thematic structure contributed by the verb *bake*: **bake′** (Baker: *x*, Bakee: *y*).

One may distinguish **individual thematic roles** from **thematic role types** (Dowty, 1989). Baker and Bakee are individual thematic roles, since they are specific to one verb. To compare the behavior of thematic roles across many verbs, linguists assign these roles to more general thematic role types such as Agent and Theme. (The term 'thematic role' is often used for such thematic role types, and will be used thus below where it does not invite confusion.) For example, the thematic roles played by the subjects of transitive *bake*, *eat*, and *sing* in (3) have in common that the individual filling the role is normally understood as purposefully causing the event to occur, hence they may be assigned the same thematic role type, one that is often called the Agent role.

(3a)	Jonas is baking the gingerbread.	**bake′** (Agent: *x*, Theme: *y*)
(3b)	Jonas is eating the gingerbread.	**eat′** (Agent: *x*, Theme: *y*)
(3c)	Marie is singing.	**sing′** (Agent: *x*)

The role played by the objects of *bake* and *eat*, often called the Theme thematic role type, involves the participant undergoing some change in virtue of the action: the gingerbread comes into existence as a result of baking (3a) and goes out of existence as a result of eating (3b).

Thematic structure is often conceived as a level of representation intermediate between semantics and syntax. For example, a thematic role type such as Agent has a rough semantic definition on the one hand (see above) and a set of characteristic syntactic properties on the other (e.g., an Agent role typically gets expressed as the grammatical subject rather than the object). Because of this intermediate status, the technical terminology specialized for thematic structure has borrowed from both the semantic and morphosyntactic sides. Terms reflecting the semantic status include the terms Agent, Theme, Goal, and so on that we used above. Terms borrowed from the side of morphological or syntactic expression include the nomenclatures of 'Deep Cases' (Fillmore, 1968; see below) and 'deep grammatical relations' such as 'logical subject/object' and 'underlying subject/object'. Proposals vary but most of them assume that this level of thematic structure has a dual status, interfacing with both semantics and syntax, but not reducible to either one.

The primary function of thematic structure for linguists is to describe and explain the complex ways in which the syntax of a clause depends on the meaning of the main verb or other predicator. A related goal is to explain semantic patterns of lexicalization, that is, to identify any universal and language-specific constraints on possible word meanings.

Pāṇini's *Kārakas*

The classical Sanskrit grammar *Aṣṭādhyāyī* ('Eight Books'), created by the Indian grammarian Pāṇini at a time variously estimated at 600 or 300 B.C. (Robins, 1979: 137) includes a sophisticated theory of thematic structure that remains influential to this day. (This section draws heavily from Kiparsky and Staal, 1969). Pāṇini's Sanskrit grammar is a system of rules for converting semantic representations of sentences into phonetic representations (Kiparsky and Staal, 1969: 84). This derivation proceeds through two intermediate stages: the level of **kāraka** relations, which are comparable to the thematic role types described above, and the level of morphosyntax (see **Figure 1**).

Grammar rules map each of the kārakas to a basic semantic relation and a basic morphosyntactic expression. More specialized variants of both types of rule are specified as well, with the basic relation and basic expression acting as defaults whenever the conditions for the variants are not met.

For example, the kāraka called *apādāna* (Source) has as its basic semantic relation 'the fixed point from which something recedes.' But with certain verbs, *apādāna* is used instead for special relations such as the source of fear, the object of hiding from, hindering,

Figure 1 Adapted from Kiparsky and Staal, 1969: 84.

or learning from, and so on. The basic expression of *apādāna* is Ablative case. The basic semantic relation of the *karman* kāraka (Theme) is 'that which is primarily desired'; its basic expression is Accusative case. The *karaṇa* kāraka (Instrument) is associated with the basic semantic relation of 'the most effective means.' While its basic expression is Instrumental case, some verbs are instead specified for the Genitive case to express the *karaṇa* (see [4] below). Other kārakas include *saṃpradāna* (Indirect Object), *adhikaraṇa* (Locative), *kartṛ* (Agent), and *hetu* (Cause).

Alternations in the expression of arguments are handled with optional rules. For example, the kāraka *karaṇa*, defined as the relation 'with the most effective means' is normally expressed with Instrumental case, as in (4a). But some verbs, such as *yajate* 'sacrifice', are associated with an optional rule specifying Genitive case for *karaṇa*, as in (4b).

(4a)	Paraśunā	vṛkṣaṃ	chinatti.
	axe.INST	tree.ACC	cuts
	'He cuts the tree with an axe.'		
(4b)	Ghṛtasya /	Ghṛtena	yajate.
	butter.INST /	butter.GEN	sacrifice
	'He sacrifices with clarified butter.'		

The more general Instrumental rule acts as a default, applying when the more specialized optional Genitive rule is not selected.

This interplay between alternative mapping rules allows the intermediate level of kārakas to greatly simplify the grammar. For example, a range of (possibly related) semantic relations map onto the *karman* kāraka. This kāraka can be expressed in a range of ways, including compounds formed with the suffix *-aN*, the Accusative case, the 'objective' use of the Genitive case, and so on. Kiparsky and Staal (1969: 110) point out that "If semantic representations were mapped directly into surface structures, without the mediating kārakas, the list of surface structures to which *karman* can correspond ... would have to be enumerated anew for each semantic relation which can underlie a *karman* relation." In short, the kārakas act as important equivalence classes for the statement of linguistic rules and generalizations. The rules for actives and passives, for impersonal passives, for infinitive verbs and nominals, for the use of particular cases, and for the interpretation of unexpressed agents of infinitives and participles are expressed in terms of the kārakas.

Thematic Roles in Modern Generative Grammar

Fillmore's (1968) Case Grammar, and much subsequent work, revived Pāṇini's proposals in a modern setting. A principle objective of Case Grammar was to identify argument positions that may have different realizations in syntax, e.g., the theme of the verb *bake* that is expressed as the object of (1a) and the subject of (2b). Fillmore argued that for many grammatical processes, the reference to purely syntactic relations such as subject and object is insufficient, and must be supplemented or even replaced by a reference to underlying semantic properties (cf. thematic role types), which he called **deep cases** or simply cases.

Fillmore hypothesized "a set of universal, presumably innate, concepts which identify certain types of judgments human beings are capable of making about the events that are going on around them" (Fillmore, 1968: 24). He posited the following preliminary list of cases, noting however that "additional cases will surely be needed" (and indeed Fillmore added more in later works):

(5a) Agent (A), the typically animate perceived instigator of the action
(5b) Instrument (I), inanimate force or object causally involved in the action or state
(5c) Dative (cvD), the animate being affected by the state or action
(5d) Factitive (F), the object or being resulting from the action or state.
(5e) Locative (L), the location or spatial orientation of the state or action
(5f) Objective (O), "the semantically most neutral case ... conceivably the concept should be limited to things which are affected by the action or state"

Fillmore provided linguistic evidence for his deep cases (for consistency they will be referred to below as thematic roles). He argued, for example, that the subjects of (6a) and (6b) have different thematic roles, namely Agent and Instrument, respectively, on the basis of facts in (6c)–(6e), assuming biuniqueness of role assignment (exactly one role per argument Noun Phrase). The unacceptable (6d) represents a failed attempt to assign both Agent and Instrument roles to the bracketed conjoined subject, while in (6e) the Instrument role is assigned to two different dependents.

(6a) John broke the window.
(6b) A hammer broke the window.
(6c) John broke the window (with a hammer).
(6d) *[John and a hammer] broke the window.
(6e) *A hammer broke the window with a chisel.
(6f) The window broke.

For the mapping from deep cases to surface syntactic structure, Fillmore introduced the influential idea of a hierarchy of preference for subject selection. He posited the following rule applying to verbs with

Agentive (A), Instrumental (I), and/or Objective (O) cases: "If there is an A, it becomes the subject; otherwise if there is an I, it becomes the subject; otherwise the subject is O" (Fillmore, 1968: 33). This rule accounts for the alternations in (6) above, assuming that the verb *break* selects O as an obligatory role while optionally selecting A and I. This mapping from semantic roles to their expression in the syntax is sometimes called **linking** or argument selection.

This notion of a universal **thematic hierarchy** relevant to linking has since reappeared in many variants (Jackendoff, 1972; Foley and Van Valin, 1984; Bresnan and Kanerva, 1989; inter alia). A relative (often partial) ordering is imposed on thematic role types and on grammatical relations, as in this simplified system:

(7a) agent > beneficiary > recipient/experiencer > instrument > theme > location
(7b) Subject > Object

Linking between these two hierarchies must respect both orders, so that, for example, in a transitive Agent/Theme verb, the Agent must link to Subject and Theme to Object, and not the other way around (i.e., the linked structure is an order isomorphism). This idea has been influential in several different syntactic frameworks. Wechsler (1995) developed this variety of hierarchical linking scheme within the framework of Head-Driven Phrase Structure Grammar. Lexical Mapping Theory (Bresnan and Kanerva, 1989 and much subsequent work) uses both absolute constraints ('Agents cannot map to objects') and relativistic ones based on a thematic hierarchy.

Pāṇini's theory of kārakas, Fillmore's Case Grammar, and other theories of thematic role types have been criticized (Dowty, 1989, 1991, *inter alia*). One problem is the difficulty of finding reliable diagnostics or definitions for the role types. Semantic criteria tend to lead to a fragmentation into finer and finer subtypes. Another problem is that a single event participant often seems to play more than one role: *John* in *John ran to the store* is arguably both the Agent (since John volitionally carries out the action) and the Theme (since he undergoes a change of location). Similarly, in the event described by *Beth bought the car from Ann for $500*, Beth has three roles: she is simultaneously the Agent, the Recipient (of the car), and the Source (of the money) (Jackendoff, 1990: 59ff). This last problem, at least, was addressed by decomposition theories, to which we turn next.

Decomposition Approaches

In the theories described so far, a verb is associated with an atomic relation (such as **break′**, **eat′**, etc.) and a simple set or list of argument roles. Theories of **lexical decomposition** expand on that model by decomposing word meaning into a structure built from more basic relations such as CAUSE, GO, STAY, and so on. The verbs *buy* and *sell*, for example, can be decomposed into the following thematic structures, where GO_{Poss} represents the transfer of possession (adapted and simplified from Jackendoff, 1990: 191):

(8a) *sell* ('α sold γ to β for δ')

$$cause\left(\alpha, \begin{bmatrix} go_{Poss}(\gamma, [from(\alpha)\ to(\beta)]) \\ go_{Poss}(\delta, [from(\beta)\ to(\alpha)]) \end{bmatrix}\right)$$

(8b) *buy* ('β bought γ from α for δ')

$$cause\left(\beta, \begin{bmatrix} go_{Poss}(\gamma, [from(\alpha)\ to(\beta)]) \\ go_{Poss}(\delta, [from(\beta)\ to(\alpha)]) \end{bmatrix}\right)$$

Variables index the argument positions, allowing a single participant to play multiple roles, as in the following example sentences:

(9a) Ann sold the car to Beth for $500.

$$cause\left(Ann, \begin{bmatrix} go_{Poss}(car, [from(Ann)\ to(Beth)]) \\ go_{Poss}(\$500, [\text{from(Beth) to(Ann)}]) \end{bmatrix}\right)$$

(9b) Beth bought the car from Ann for $500.

$$cause\left(Beth, \begin{bmatrix} go_{Poss}(car, [from(Ann)\ to(Beth)]) \\ go_{Poss}(\$500, [\text{from(Beth) to(Ann)}]) \end{bmatrix}\right)$$

Notice that the structures for *buy* and *sell* in (8) are the same except for the identity of the first argument of CAUSE. This reflects the fact that (9a) and (9b) are paraphrases (or very nearly so), differing only with respect to the primary instigator of the event (Jackendoff, 1990: 191).

The structures in (8)–(9) illustrate a **localist** approach, in which various abstract relations such as possession are analyzed as metaphorical extensions of locative relations (Gruber, 1965; Jackendoff, 1972). Relations such as GO apply across different semantic fields, the most basic being spatial location and movement, where GO encodes literal motion in space. Within the field of possession relations, GO_{Poss} indicates transfer of possession (the semantic field is indicated by the subscript). *see* **Lexical Conceptual Structure** for more on Jackendoff's decomposition theory generally, and the localist hypothesis in particular.

Gruber (1965) hypothesized that all semantic relations are generalizations of spatial and motional relations. Jackendoff (1990: 125ff) argued that this reduction was inadequate and supplemented the localist structure with other relations such as

AFF(ect), a two-place relation between an Actor (the one that affects) and Patient (the one that is affected). Inspired by autosegmental phonology, Jackendoff represented relations on two autonomous tiers, the thematic tier for local relations and their derivatives, and the action tier for the roles Actor and Patient. In another tier-based proposal, Grimshaw (1990) posited a thematic tier that contains thematic roles such as Agent, Experiencer, Goal/Source/Location, and Theme, and an aspectual tier that expresses causation and change of state.

Aspectual Decomposition

An influential decomposition approach to word meaning is presented in Dowty, 1979. Dowty combined insights developed in Generative Semantics (see 'Composing Complex Word Meaning in the Syntax' below) with the intensional logic system in the tradition of Richard Montague. He focused on deriving the aspectual classes of verbs due to Vendler (1957), namely states, activities, accomplishments, and achievements. States (*know, love, be happy*) do not involve change, in contrast to the other three categories, which do. Activity predicates (*run, push a cart*) denote indefinite change of state, while the remaining nonstative classes denote definite changes with an inherent endpoint. Accomplishments (*paint a picture, make a chair*) are complex and extended in time, while achievements (*spot, find, die*) are simple and occur at a point in time.

Dowty (1979) hypothesized that "the different aspectual properties of the various kinds of verbs can be explained by postulating a single homogeneous class of predicates – stative predicates – plus three or four sentential operators and connectives." (Dowty, 1979: 71) The operators and connectives are treated as logical constants, with a standard model-theoretic interpretation for each. Two important operators are CAUSE and BECOME. Accomplishments are defined in terms of the operator CAUSE, which takes two propositions as arguments. As its name suggests, this operator is meant to capture the notion of causation. The BECOME operator takes a single state as its scope, its interpretation fixed so that BECOME(p) is true at time t if $\neg p$ is true just prior to t and p is true just after t. This operator is introduced by accomplishment verbs, and the state p corresponds to the result state of the accomplishment. A third operator, DO, relates volitional agents to the actions they undertake.

Dowty illustrated his system with detailed analyses, including a treatment of the systematic semantic relation between adjectives such as *cool* or *open*, and their cognate inchoative and transitive verbs. For example, the property **cool**′ is the stative predicate expressed by the adjective *cool* (10a). (The logical expressions in (10) are adapted in simplified form from Dowty, 1979: 206–207). The inchoative verb *cool*, as in *The soup cooled*, is translated using **cool**′ in combination with the BECOME operator in (10b). This sentence can be roughly paraphrased as 'The soup became cool.' Dowty's translation of the causative verb *cool*, as in *Marie cooled the soup*, is an expression of the form ϕ CAUSE ψ, where ϕ and ψ are propositions (10c). The causing proposition ϕ involves the agent argument (*Marie*, in the example) and the result ψ is BECOME(**cool**′ (the-soup)).

(10a) adjective *cool* (as in *The soup is cool*):
λy [**cool**′ (y)]

(10b) intransitive verb *cool* (as in *The soup cooled*):
λy [BECOME[**cool**′ (y)]]

(10c) transitive verb *cool* (as in *Marie cooled the soup*):
$\lambda y \lambda x$[[. . .x . . .] CAUSE [BECOME[**cool**′ (y)]]]

Dowty motivated his system with a rich array of linguistic evidence. For example, the existence of the result state expression **cool**′ (y) in the structure in (10b) and (10c) explains the ambiguity of *Marie cooled the soup again*: it presupposes either (a) that Marie cooled the soup at least once before, or (b) that the soup was cool before. (Reading (b) is illustrated by the familiar rhyme, *All the king's horses and all the king's men couldn't put Humpty Dumpty together again*. Dowty (1979: 252) notes that this "is obviously not intended to entail that anyone had put Humpty Dumpty together on an earlier occasion, but merely that Humpty Dumpty had been 'together' once before.") This ambiguity follows if the operator introduced by the adverb *again*, which contributes the presupposition that the situation in its scope obtained previously, can take a scope that is either wider or narrower than that of the BECOME operator.

Unlike Pāṇini, Fillmore, and Jackendoff, Dowty did not apply his theory to the linking between lexical semantics and syntax, such as subject selection. Dowty does not posit rules of the form 'a variable contained within the first argument of CAUSE must be linked to the subject.' Nor would such rules make sense, under Dowty's assumptions. The expressions of intensional logic do not constitute a linguistic level of representation, since various parts of them can effectively be traded in for meaning postulates without affecting the resulting interpretation. Dowty's main hypothesis – that all verb meanings can be reduced to states together with a small set of primitive semantic operations – does not require that there be a unique translation of each linguistic expression into intensional logic, but only that there be at least one translation (Dowty, 1979: 199).

However, other researchers have adopted a reified version of Dowty's logical expressions as a basis for linking theories. Foley and Van Valin (1984), for example, posited logical structures based on Dowty, 1979. A table of universal correspondences maps these positions in logical structure onto the two Macro-Roles Actor and Undergoer, and these in turn are mapped onto the morphosyntax of the sentence.

An interesting variant of such approaches to linking derives linking patterns from the depth of embedding in the logical form (Bierwisch and Schreuder, 1992; Wunderlich, 1997). Bierwisch and Wunderlich represent grammatically relevant aspects of lexical decomposition in a semantic form, as they call it, built from universal operators such as CAUSE and BECOME as above. The arguments of a verb are ranked according to their relative level of embeddedness in the semantic form. Wunderlich (1997) refers to the ranked set of arguments, elaborated with some nonsemantic information, as the thematic structure. For example, in a semantic form similar to (10c) above, the variable *x* would outrank *y*, since *y* is the more deeply embedded (this is a simplification; see Wunderlich, 1997 for details). This ranking determines the mapping to grammatical relations such as subject and object, much as the thematic hierarchy does in the system presented in (7) above, only it is unnecessary to stipulate a hierarchy since the ranking is derived from the semantic form.

Proto-Roles and Macro-Roles

Dowty (1991) proposed a theory of linking based on prototype theory. The idea behind his proto-role approach is that there are really only two thematic-role-like concepts involved in argument selection, and these are 'cluster concepts,' not discretely defined ones. He calls them the Agent Proto-Role and Patient Proto-Role. These are to be the (only) thematic categories on which linking principles are stated. These are the specific properties Dowty (1991: 572) gives:

(11) Contributing properties for the Agent Proto-Role:
a. volitional involvement in the event or state
b. sentience (and/or perception)
c. causing an event or change of state in another participant
d. movement (relative to the position of another participant)
(e. exists independently of the event named by the verb)

(12) Contributing properties for the Patient Proto-Role:
a. undergoes change of state
b. incremental theme
c. causally affected by another participant
d. stationary relative to movement of another participant
(e. does not exist independently of the event, or not at all)

The properties are prototypical: no single property is essential for either role. Instead, Dowty gives the following procedure:

(13) Argument selection principle: in predicates with grammatical subject and object, the argument for which the predicate entails the greatest number of Proto-Agent properties will be lexicalized as the subject of the predicate; the argument having the greatest number of Proto-Patient entailments will be lexicalized as the direct object. (Dowty, 1991: 576)

Notice that there is no attempt to find some unifying semantics behind the lists of properties in (11) and (12). Proto-Agent and Proto-Patient are 'cluster concepts' or 'higher-order generalizations about meanings' that need not even be considered as part of the competence grammar. Instead, Dowty suggests that the argument selection principle (13) acts as a default in the acquisition of lexical items.

A number of linguists have borrowed aspects of the proto-role idea into their models of competence grammar (Ackerman and Moore, 1999; Davis, 2001). Davis's (2001) theory of linking between word meaning and syntax uses proto-role properties in a multiple inheritance type hierarchy in the Head-Driven Phrase Structure Grammar framework. Each proto-role property is encoded in the lexicon as a type within a rich hierarchy of types and subtypes. Davis assumes two 'macro-roles' called Actor and Undergoer (following the terminology of Foley and Van Valin, 1984), which are, for Davis, reified versions of Dowty's (1991) Proto-Agent and Proto-Patient cluster concepts, respectively. For example, corresponding to (11c) ('causing an event or change of state in another participant') and (12c) ('causally affected by another participant') is an abstract 'affect' relation with two arguments, Actor and Undergoer. This semantic relation takes its place within a hierarchy of relations of increasing specificity. Particular verbs inherit semantic information from those types, and thereby also inherit the classification of roles into the two macro-roles, which determines the linking to the syntax.

Composing Complex Word Meaning in the Syntax

Complementing the theories of lexical decomposition is the idea that apparently complex word meanings are composed within the combinatorial syntax itself.

This recurring theme has resurfaced in generative syntax under different guises.

An early version of this theme appeared in the 1960s under the rubric of Generative Semantics (Lakoff, 1965; McCawley, 1968). Semantically contentful primes such as CAUSE and BECOME are directly inserted into syntactic deep structure representations of the sentence meaning. For example, the systematic relation between the adjectival, intransitive, and transitive forms, as in (10) above, was derived by positing distinct though related deep structures for the sentences, analogous to the logical expressions for word meaning in (10) (as noted above, Generative Semantics was one inspiration for Dowty's 1979 analysis).

Although Generative Semantics itself died out, vestiges of the syntactic composition approach to word meaning survived, and later returned in full force. It is noteworthy that even Chomsky's (1970) influential article 'Remarks on Nominalization,' which persuasively argued *against* using transformations to capture relations between derivational cognates such as *destroy/destruction*, still posited an abstract CAUSE node in syntax for the derivation of causative variants of verbs (Chomsky, 1970: 24ff; example [12]).

In later variants of transformational grammar such as Government/Binding Theory, Deep Structure (or D-structure, as it came to be called) lost its status as a true semantic representation, but remained a representation of thematic structure (Chomsky, 1981: Chap. 2, Sect. 2.2). The idea was that a particular thematic role of a lexeme must be consistently assigned to the same position in phrase structure. One formulation of this conception was Baker's (1988) Uniformity of Theta Assignment Hypothesis (UTAH, [14]). Baker illustrated with the alternation in (15).

(14) Identical thematic relationships between items are represented by identical structural relationships between those items at the level of D-structure. (Baker, 1988: 46)

(15a) Julia melted the ice cream into mush.
(15b) The ice cream melted into mush.

Since the thematic relationship between *melted* and *the ice cream* is the same in (15a) and (15b), it follows from UTAH that they must be in the same relative positions at D-structure. Specifically, the NP *the ice cream* is the (D-structure) object of the verb in both sentences. Baker posits the following D-structures for (15a) and (15b), respectively:

(16a) $[_{S}$ Julia $[_{VP}$ melted [the ice cream] into mush]].
(16b) $[_{S}$*e* $[_{VP}$ melted [the ice cream] into mush]].

To derive sentence (15b), a transformation moves the NP *the ice cream* into the subject position, where it replaces the empty element marked by *e*. In Government Binding theory, D-structure functioned as a kind of thematic structure for the sentence.

The Generative Semantics idea of building complex word meaning by combining simpler semantic elements within the syntax was revived in the 1990s, but it remains highly controversial. In one influential proposal, Hale and Keyser (1993) derive denominal verbs such as *paint* and *shelve* from a syntactic structure containing the cognate nouns *paint* and *shelf*.

(17a) We painted the house.
(17b) We $[_{V'}$ V1 $[_{VP}$ house $[_{V'}$ V2 $[_{PP}$ P_{with} paint]]]].

(18a) We shelved the books.
(18b) We $[_{V'}$ V1 $[_{VP}$ books $[_{V'}$ V2 $[_{PP}$ P_{on} shelf]]]].

The nominal root *paint* or *shelf* moves to the empty verb position V1, combining en route with the abstract silent preposition shown here as P_{with} (cp. 'provide the house with paint') or P_{on} (cp. 'put books on the shelf'); and with an abstract silent verb in V2.

But the success of that analysis is disputed in a detailed critique by Kiparsky (1997). Kiparsky argued that the derivation of such verbs from nouns is conditioned by conceptual knowledge about the noun, information assumed to be absent from the syntax-like structures posited by Hale and Keyser. Kiparsky noted, first of all, that Hale and Keyser's proposed system fails to prevent the insertion of the noun root into the wrong structure. For example, substituting *paint* for *books* and *house* for *shelf* in (18b) yields a structure that would mean 'cause paint to go on the house' – that is, 'paint the house'. But this wrongly leads to the generation of the unwanted sentence **We housed the paint*. Hence Hale and Keyser do not actually predict whether the denominal verb is named for the location (shelf, etc.) or the locatum (paint, etc). Kiparsky (1997: 482) specifies a simple principle to do just that: "If an action is named after a thing, it involves a canonical use of the thing." It is a canonical use of paint to put it on houses, so the action (to paint) is named after the thing (paint); but it is not a canonical use of houses to put paint on them. This explanation crucially depends upon conceptual information that is associated with the words but absent from the syntactic or semantic form. Thus noun-to-verb conversion is a lexical and not a syntactic process.

In another influential proposal to build word meaning in the syntax, Kratzer (1996) hypothesized that the external arguments (Williams, 1981) – roughly the Agent thematic roles – are not selected by the verb at all. For Kratzer (1996), the verb *buy*

lacks a buyer argument, hence in the sentence *Sue bought the doll*, the subject *Sue* is not an argument of the verb *buy*. Instead the agent role is assigned in the syntax by what is sometimes characterized as an abstract light verb or secondary predicate.

In an actual light verb construction such as *John will do the laundry*, most of the semantic content describing the laundering event is carried by the noun *laundry*, while the light verb *do* merely serves to introduce the subject (*John*), which expresses the agent of that event. Notating the abstract light verb with lowercase *v* (Chomsky, 1995: 315), the underlying syntactic structure of *Sue bought the doll* is shown in (19a). This structure is intuitively analogous to the (somewhat awkward) sentence (19b), provided here for illustrative purposes.

(19a) [Sue [*v* [bought the doll]]]
(19b) [Sue [did [the purchase of the doll]]]
(19c) $\exists$e[buy(the-doll, e) $\wedge$ Agent(Sue, e)]

Kratzer's logical form for the sentence, shown in (19c), is a modification of the event semantics analysis due to Davidson (1967). Davidson argued that an action sentence asserts the existence of an event, indicated by the variable *e*, which is bound by the existential quantifier ($\exists$). Kratzer hypothesized that in composing the semantic form in (19c) from the sentence structure in (19a), the expression **buy**(the-doll, e) comes from the verb *bought* (and its argument, the NP *the doll*), while the expression **Agent**(Sue, e) is provided by *v* (and its argument, the NP *Sue*). Note that this use of the abstract light verb is similar to the use of semantic primes such as CAUSE in the theories that compose word meaning in the syntax. One innovation introduced in this most recent revival of Generative Semantics has been the attempt to assimilate the abstract semantic primes into the system of functional heads in extended X-bar theory.

Kratzer's proposal that agent arguments are not selected by the verb has been widely adopted but remains highly controversial. One challenge for Kratzer is to explain why verbs vary as to whether they can, must, or cannot appear with an agent argument:

(20a) John dissolved the company. / The company dissolved.
(20b) John eliminated the company. / *The company eliminated.
(20c) *John disappeared the rabbit. / The rabbit disappeared.

Even restricting our attention to verbs that select an agent argument, the proposal still encounters problems. Krifka (1999) attacks the idea of representing lexical semantics in syntactic terms by showing that many verbs of causation impose special semantic conditions on the relation between the causing and resulting events. This supposition allows an elegant account of certain observed constraints on the dative alternation (e.g., *Sue threw/pulled the box to Ann; Sue threw/*pulled Ann the box*). But Krifka notes that this account is possible only if those semantic conditions, and hence the causing event itself, are specified in the lexical entry of the verb.

The question of whether word meaning is assembled in the lexicon or the syntax remains controversial.

Thematics is the study of themes and motifs in text and discourse. It deals with textual elements and the inferences and processes underlying their construction and maintenance. Because the elements, inferences, and processes lie at the crossroads of various disciplines, the study of themes must be carried out at the interface of these disciplines, including linguistics, psychology, cognitive science, (art) history, and literary studies. For instance, in literary studies and art history, the nature, occurrence, and development of popular motifs and themes have been documented (Daemmrich and Daemmrich, 1986), the constant elements of theme have been compared to the variable elements in literary text (Zholkovsky, 1984), and historical, social, and cultural aspects of theme have been visited and revisited (Bremond *et al.*, 1995; Sollors, 1993). In text linguistics the textual features that contribute to theme have been analyzed (Emmott, 1997; van Dijk, 1980; van Peer, 1986). In psychology cognitive processes that are active in constructing the theme of the text have been investigated (Gernsbacher, 1994; Graesser *et al.*, 2003), whereas in computational linguistics various attempts have been made to automatically summarize and retrieve themes in text (Jurafsky and Martin, 2000). In sum, thematics has grown to highly interdisciplinary studies of 'aboutness' in text (Louwerse and van Peer, 2002).

Theme and Motifs

Theme refers to what a text or discourse is about, its main idea, its subject or topic. Several other terms are somewhat synonymous to theme, including *topos*, *Stoff* (as in *Stoffgeschichte), figure*, *topic*, *gist*, *upshot*, and *point*. Themes are often related to some human activity, are directly involved in human interests and concerns, or tend to be emotionally charged. Textbook examples of themes are illusion versus reality (*Madame Bovary*; *Hamlet*); marriage, love, and family life (*Anna Karenina*); or a journey of discovery (*Ulysses*). In addition to the meaning of aboutness, theme has sometimes been considered to be related only to the doctrinal content of a text. A clear example concerns fables, where the theme would be the moral of the text.

Related to theme is the notion of motif, the smallest event units in a text (e.g., the hero died, the letter

Thematics is the study of themes and motifs in text and discourse. It deals with textual elements and the inferences and processes underlying their construction and maintenance. Because the elements, inferences, and processes lie at the crossroads of various disciplines, the study of themes must be carried out at the interface of these disciplines, including linguistics, psychology, cognitive science, (art) history, and literary studies. For instance, in literary studies and art history, the nature, occurrence, and development of popular motifs and themes have been documented (Daemmrich and Daemmrich, 1986), the constant elements of theme have been compared to the variable elements in literary text (Zholkovsky, 1984), and historical, social, and cultural aspects of theme have been visited and revisited (Bremond *et al.*, 1995; Sollors, 1993). In text linguistics the textual features that contribute to theme have been analyzed (Emmott, 1997; van Dijk, 1980; van Peer, 1986). In psychology cognitive processes that are active in constructing the theme of the text have been investigated (Gernsbacher, 1994; Graesser *et al.*, 2003), whereas in computational linguistics various attempts have been made to automatically summarize and retrieve themes in text (Jurafsky and Martin, 2000). In sum, thematics has grown to highly interdisciplinary studies of 'aboutness' in text (Louwerse and van Peer, 2002).

Theme and Motifs

Theme refers to what a text or discourse is about, its main idea, its subject or topic. Several other terms are somewhat synonymous to theme, including *topos*, *Stoff* (as in *Stoffgeschichte), figure*, *topic*, *gist*, *upshot*, and *point*. Themes are often related to some human activity, are directly involved in human interests and concerns, or tend to be emotionally charged. Textbook examples of themes are illusion versus reality (*Madame Bovary*; *Hamlet*); marriage, love, and family life (*Anna Karenina*); or a journey of discovery (*Ulysses*). In addition to the meaning of aboutness, theme has sometimes been considered to be related only to the doctrinal content of a text. A clear example concerns fables, where the theme would be the moral of the text.

Related to theme is the notion of motif, the smallest event units in a text (e.g., the hero died, the letter

arrived). Motifs can be subdivided into bound and free motifs. Bound motifs are essential to the logical-chronological development of a text (generally a story), whereas free motifs are not essential to the story line. Another distinction between motifs is the one between static and dynamic motifs. The former are, for instance, states of the character (whether necessary or not for the story line), whereas the latter are actions (Barthes, 1970; Tomashevsky, 1925/1965).

History of Thematics

The study of theme can be traced back to Plato's *Ion* (ca. 390 B.C.E.), Aristotle's *Poetics* (ca. 335 B.C.E.), and Horace's *Art of Poetry* (ca. 14 B.C.E.) and has received continuous attention throughout the centuries. The term *thematics* was coined in 1925 by Tomashevsky (English translation 1965) in his article 'Thematics.' Tomashevsky claimed that many texts can have one theme, but that one text can also have many themes. In the tradition of Russian Formalism, Tomashevsky tried to isolate and define the formal properties of poetic language and argued that the theme of a text is the sum of the meanings of its elements. More precisely, the themes (or motifs) of the text form the building blocks of texts.

The impetus in thematic research came from folklorists. In a Positivist tradition, they looked for the universality of folktales and identified recurrent patterns. Bédier (1893), for instance, made the distinction between constant and variable components in folktales, where the former form the basis of the story. The constant and variable building blocks of a story resulted in a number of motif indices (e.g., Veselóvsky, 1913) that were very different from those that classified according to the historical relationship stories had to each other (e.g., Aarne, 1910). Aarne's *Types of the Folk-tale* was originally an historical index, but was revised by Thompson using the smaller elements of a story (motifs) that did not imply the historical connection. The result was the influential Aarne–Thompson (1928) index that brought together narrative elements from a wide range of traditional fictional narratives. Later, Thompson's six-volume *Motif-Index of Folk-literature* (1955–1958) classified motifs into smaller classes such as actors (e.g., wicked stepmother), objects (e.g., seven-league-boots), and single incidents (e.g., to die next day).

The Aarne and Thompson classifications proved to be very useful for practical references, but lacked a theoretical basis. Such a basis was provided by Vladimir Propp's *Morphology of the Folktale* (original 1928; English translation 1958), which undoubtedly influenced the interdisciplinary study of themes most. Many of the methodological problems Propp identified directly relate to today's state of thematics. Propp argued, for instance, that classifying texts is problematic because of the methods of investigation and argues that only an interdisciplinary approach can bring solutions. More specifically, Propp claimed that previous classifications with a clear-cut *a priori* division into which the various tales under investigation are classified are problematic. Propp argued that motifs are the primary building blocks of a tale, whereas the plot is a creative unifying act. This means that a set of motifs forms the constants of a tale, to which variables are added. The problem, however, is to decide what these constants are. Instead of using a deductive approach, where the constants are defined before the actual study of the tales has started, Propp compared the plots of a corpus of tales by abstracting each tale's constant elements from the variable ones. These constant elements are what Propp called 'functions,' acts of a character that are important for the course of the action in the text. The advantage of such a method is that the varieties on Aarne and Thompson's paradigmatic plane are reduced by working on a syntagmatic plane. More concretely, many folklorists see a motif such as 'a dragon kidnaps the tsar's daughter' as a basic narrative unit. Propp, on the other hand, argued that this example can be further decomposed into four elements, which can in fact vary. The dragon can be replaced by all kinds of villains, the abduction by all kinds of acts of disappearance, the tsar by any powerful ruler, or the princess by any kind of victim.

Although one could argue that thematics has never lacked interest, in the 1970s and 1980s it lost its momentum somewhat, at least in literary studies. The treatment of themes in a systematic text-centered way and the confusion regarding its terminology (Levin, 1968) resulted in a movement away from thematic criticism in literary studies. Some, however, continued their work in thematics (see following discussion). More recently, the interest in the study of themes has picked up again, primarily because of the interdisciplinary interest in the study of theme (Bremond *et al.*, 1995; Louwerse and van Peer, 2002; Sollors, 1993; Trommler, 1995). Thematics has grown to become an interdisciplinary line of research, with studies on theme in literary studies, art history and music, text linguistics, psychology, and computational linguistics. We will briefly outline some of the leading work in each of these areas, fully acknowledging that by dividing the overview into disciplines we do not do justice to the interdisciplinary nature of thematics.

Text Linguistics

The object of thematics is somewhat different from the notion of theme as distinguished from rheme. In linguistics and psycholinguistics the distinction between theme and rheme (also referred to as given and new, topic and comment) has played an important role. In the 1920s linguists of the Prague School introduced the distinction between theme and rheme, theme being the given information, used by the speaker to either introduce or maintain a particular topic. The rheme is the new information, that is, the expression containing the information the speaker wishes to communicate with respect to the topic at hand. In a similar vein, theme in functional grammar is selected by the speaker to ground what is going to be said, the point of departure (Halliday, 1985). This notion of theme is related to that of theme used in thematics, with the important difference that in thematics, theme refers to the aboutness of text units beyond the sentence (typically paragraph, chapter, text, or several texts).

This last notion of theme became popular in text linguistics with the English translation of Propp's *Morphology of the Folktale* (1958). Around this time various linguists argued for global structures in narrative (Bierwisch, 1965; Harris, 1968), followed by transformational rules for story and text grammars (Van Dijk, 1972, 1980). van Dijk, for instance, proposed that macrorules like addition, selection, deletion, and construction are applied to the textual surface structure. These rules filter the text and keep its gist, the macrostructure. In other words, the macrostructure of a text can guide the reader in determining the theme of the text (*see* **Macrostructure**). In fact, certain linguistic cues and structures can help identify these global structures (Givón, 1993).

Other text linguists have argued that it is not just the presence of these linguistic cues that can create thematic meaning, but also how these cues are used (see Emmott, 1997). Stylisticians generally use the term *foregrounding* when the text draws attention to the linguistic medium because of its unusual use (van Peer, 1986). Repeated use of certain linguistic structures or stylistic figures will not only emphasize the literariness of the text, but also its thematic meaning.

Literary Studies

For a long time the object of thematics was primarily reserved for literary themes, including those in folktales. Although the distinction between thematics in literary studies and in other disciplines is not clear cut, literary studies has clearly had its own thematic tradition. Levin (1968), for instance, pointed out the importance of the textual units in a text, but showed that thematics in the literary tradition has primarily been historically oriented. Elisséef (1949) documented a theme and motif index in *Thousand and One Nights*, whereas Daemmrich and Daemmrich (1986) compared recurrent themes in literature, resulting in a large index of themes and motifs and their occurrences in western literature. Other examples of these indices are Amoia and Knapp (2002) identifying multicultural themes, Brunel (1992) listing mythological themes, Magill (1986) identifying themes in drama, and Zipes (2000) indexing themes in fairy tales.

No doubt in part caused by Formalist and Structuralist approaches becoming influential in the English- and French-speaking world in the seventies (Barthes, 1970; Bremond, 1973; Propp, 1958; Thomashevsky, 1925/1965), a gradual shift toward text-centered approaches can be noticed in the study of themes. At the time when poststructuralism became fashionable in literary studies, Zholkovsky (1984) and Ziolkovski (1983) distanced themselves from these movements and linked thematics back to a prepoststructuralist poetics, showing how Formalism and Structuralism can go hand in hand with thematics, arguing that generic themes in literature come about through the structure of the text. However, whereas in text linguistics and psychology, the attention for textual thematic features in the text increased, thematics in literary studies became marginalized. This changed with the volumes by Bremond *et al.* (1995), Sollors (1993), and Trommler (1995), in part perhaps because these volumes include a variety of approaches in the field of literary studies and (art) history.

Cross-Cultural Psychology

Recently, another dimension of thematics has been added from the field of cross-cultural psychology. Cultural differences and similarities are seen as reflected in different and similar themes that play a dominant role in those cultures. Around such themes patterns of shared beliefs, norms, and values are organized into cultural syndromes (Triandis, 1996). Examples of such syndromes are collectivism, individualism, honor, and tightness. In collectivist cultures, for instance, the self is predominantly defined with reference to others in the social group, whereas individualist cultures define the self in more autonomous terms. It is obvious that the theme of self uses different forms of social space, goal structures, or emotions. Cross-cultural psychologists have developed methods to study and measure the underlying themes of cultural syndromes (Triandis *et al.*, 1990). In order to start developing such a cross-cultural psychology, we need to study the differences between cultures. One way to do this is by looking at the way

in which culturally defined themes construct cultural syndromes.

Psycholinguistics

One of the first thematics studies in psychology investigated the facilitating role of memory for themes (Bransford and Johnson, 1972). When participants were given a rather vague and ambiguous text without a clear theme, recall was inferior compared to the condition where participants were instructed what the text was about. The role of theme in memory was also found with more natural (less vague and ambiguous texts) texts (Anderson and Pichert, 1978).

Several studies have found that text processing involves three processing levels: the surface form (the meaning of the text with its linguistic structure), the propositional representation of the surface form (the meaning of the text), and the situation model (the meaning of the text integrated with the reader's background knowledge) (Kintsch, 1998). The surface level representation decays from memory relatively quickly. The propositional level, which contains the meaningful thematic units primarily derived from the text, decays from memory next. The situation model, which is most likely to contain all relevant thematic information, is retained in memory best (Kintsch *et al.*, 1990). Various text processing theories have been able to predict which parts of the text are remembered best and why (van Dijk and Kintsch, 1983). All studies indicate that theme content decays from memory more slowly than other processing levels (Kintsch *et al.*, 1990).

There is also some thematic research in the field of neuropsychology. Despite the fact that it is hard to determine where the processing of themes takes place in the brain (given that there are so many lower- and higher-level cognitive processes active at the same time) literature suggests that many of the processes involved in retrieving the theme of the text can be located in the right hemisphere (Nichelli *et al.*, 1995).

Computational Linguistics

A line of thematics that is relatively new concerns computational approaches to the study of theme. Although there is no computational model available that plucks out the theme of a text, several models approximate what the text is about. Some models center around the frequency of semantic fields in a text. Examples of such models are PROTAN (PROTocol Analyzer), which creates profiles of the main affective connotations in the text and analyzes relations between the words in the text to determine themes (Hogenraad, 2002), and ALEXIS (Martindale, 1990), using the Regressive Imagery Dictionary to measure thematic primordial content and conceptual thought.

A different direction in computational thematics comes from work that builds onto story grammars (Rumelhart, 1977). Initially these story grammars consisted of rule systems that could account for major events in conventional stories. A typical rule would state that a story consisted of an introduction, climax, and conclusion. This work expanded with the work on scripts (Schank and Abelson, 1977), generic knowledge structures like restaurant scripts that activate typical events in a restaurant, the work on goals of the characters in the text (Wilensky, 1983), and the work on affect in characters in Lehnert's (1981) plot unit analysis. Dyer (1983) developed these theories further by introducing thematic abstraction units (TAUs), knowledge structures for understanding events. TAUs are more abstract than Schank and Abelson's (1977) scripts, in that they incorporate the agents' plans and goals. TAUs would allow to generate a complex knowledge dependency structure of plans, failed plans, and attempted recovery of plans.

More recently, computational models have been developed that identify cohesion relations between events in a text in order to compute the most cohesive, and therefore most salient, thematic events (Louwerse, 2002). A slightly different approach was taken by Kintsch (2002), who used Latent Semantic Analysis to represent events in a text as vectors in a high-dimensional space, allowing to derive a precise mathematical representation of the theme of the text.

Interdisciplinary Studies and Future Directions

Thematics has primarily focused on narrative texts, in part because narratives tend to be more homogeneous and in part because of the background of thematics in literary studies. Looking at the history of thematics, some (Bremond *et al.*, 1995; Sollors, 1993) have claimed that thematics was present and absent at different time periods. The argument should be made, however, that thematics has never disappeared from disciplines such as literary studies, text linguistics, psychology, and computational linguistics. With the current efforts to integrate these various approaches (Louwerse and van Peer, 2002), the study of theme has thereby become even more influential and more intercultural as well as interdisciplinary.

Starting Points

The special status of the opening constituent(s) of sentences in the signaling of discourse organization has long been recognized, particularly within applied studies oriented toward the teaching of writing (see, e.g., Vande Kopple, 1991; Hewings, 2004); and scholars from a variety of backgrounds have investigated the textual implications of placing certain kinds of constituents in initial position (e.g., Thompson, 1985, on purpose clauses; Schiffrin, 1985, on causal sequences; Kies, 1986, on left dislocations). The phenomenon has been most fully theorized within Systemic Functional Grammar under the label of Theme (Halliday, 1967/1968, 1985/1994/2004), and the majority of recent studies of Theme in text operate within this approach. The account given here will therefore mainly draw on the Systemic Functional model.

Identifying Theme

It is useful to begin by providing a brief sketch of how Theme is identified in this model. Halliday (e.g., 1994: 53) views Theme (in English) as comprising everything up to and including the first experiential ('content') constituent of a clause. Anything following the Theme in the clause is termed Rheme. Example 1 illustrates some of the basic categories – the Themes are underlined:

(1) [1] Rover joined our household entirely at random. [2] But the relationship with him was entirely satisfying. [3] When you have a dog, you put in food and attention, [4] and what you get out is unconditional affection and respect. [5] Of course, animal behaviourists see this as no more than pack instinct.

In three of these sentences, the first experiential constituent is simultaneously Subject and Theme. In Halliday's terms, this is 'unmarked Theme': the choice that is made unless there are particular reasons for choosing something other than Subject as Theme. In [1] this constituent comprises the whole of Theme; in [2] the experiential constituent *the relationship with him* is preceded by a textual element, the conjunction *but*; and in [5] the experiential constituent *animal behaviourists* is preceded by an interpersonal element, the disjunct *of course* ([2] and [5] are therefore cases of 'multiple Theme' in Halliday's terms). In [3] the Theme is a 'marked Theme' (i.e., non-Subject Theme), realized by an initial adverbial clause. The Theme of [4] consists of a textual conjunction *and* followed by an embedded clause functioning as Subject in a WH-cleft structure. Halliday calls this latter type a thematic equative, whereas Fawcett and Huang (1995) have coined the term 'enhanced Theme' for this and a range of other Theme types, which appear to lie outside the unmarked/marked distinction.

There are a number of complications in this deceptively simple picture, which particularly affect decisions on where the boundary between Theme and Rheme should be placed. Two complicating factors that are especially relevant to thematic analyses of texts are the status of Subject following a marked Theme, and the presence of grammatical metaphor. A number of analysts (e.g., Enkvist, 1973; Downing, 1991; Davies, 1997) argue that marked Themes perform different textual functions from unmarked Themes, and that therefore, if, as typically happens, the Subject follows immediately after a marked Theme, this also should be included as the unmarked Theme. Thus, in sentence [3] of example 1 above, the Theme would be *When you have a dog, you*.

Grammatical metaphor (Halliday and Matthiessen, 2004: Chapter 10) comes into play, especially in

Starting Points

The special status of the opening constituent(s) of sentences in the signaling of discourse organization has long been recognized, particularly within applied studies oriented toward the teaching of writing (see, e.g., Vande Kopple, 1991; Hewings, 2004); and scholars from a variety of backgrounds have investigated the textual implications of placing certain kinds of constituents in initial position (e.g., Thompson, 1985, on purpose clauses; Schiffrin, 1985, on causal sequences; Kies, 1986, on left dislocations). The phenomenon has been most fully theorized within Systemic Functional Grammar under the label of Theme (Halliday, 1967/1968, 1985/1994/2004), and the majority of recent studies of Theme in text operate within this approach. The account given here will therefore mainly draw on the Systemic Functional model.

Identifying Theme

It is useful to begin by providing a brief sketch of how Theme is identified in this model. Halliday (e.g., 1994: 53) views Theme (in English) as comprising everything up to and including the first experiential ('content') constituent of a clause. Anything following the Theme in the clause is termed Rheme. Example 1 illustrates some of the basic categories – the Themes are underlined:

(1) [1] Rover joined our household entirely at random. [2] But the relationship with him was entirely satisfying. [3] When you have a dog, you put in food and attention, [4] and what you get out is unconditional affection and respect. [5] Of course, animal behaviourists see this as no more than pack instinct.

In three of these sentences, the first experiential constituent is simultaneously Subject and Theme. In Halliday's terms, this is 'unmarked Theme': the choice that is made unless there are particular reasons for choosing something other than Subject as Theme. In [1] this constituent comprises the whole of Theme; in [2] the experiential constituent *the relationship with him* is preceded by a textual element, the conjunction *but*; and in [5] the experiential constituent *animal behaviourists* is preceded by an interpersonal element, the disjunct *of course* ([2] and [5] are therefore cases of 'multiple Theme' in Halliday's terms). In [3] the Theme is a 'marked Theme' (i.e., non-Subject Theme), realized by an initial adverbial clause. The Theme of [4] consists of a textual conjunction *and* followed by an embedded clause functioning as Subject in a WH-cleft structure. Halliday calls this latter type a thematic equative, whereas Fawcett and Huang (1995) have coined the term 'enhanced Theme' for this and a range of other Theme types, which appear to lie outside the unmarked/marked distinction.

There are a number of complications in this deceptively simple picture, which particularly affect decisions on where the boundary between Theme and Rheme should be placed. Two complicating factors that are especially relevant to thematic analyses of texts are the status of Subject following a marked Theme, and the presence of grammatical metaphor. A number of analysts (e.g., Enkvist, 1973; Downing, 1991; Davies, 1997) argue that marked Themes perform different textual functions from unmarked Themes, and that therefore, if, as typically happens, the Subject follows immediately after a marked Theme, this also should be included as the unmarked Theme. Thus, in sentence [3] of example 1 above, the Theme would be *When you have a dog, you*.

Grammatical metaphor (Halliday and Matthiessen, 2004: Chapter 10) comes into play, especially in

relation to interpersonal meanings. These are congruently expressed through choices in interpersonal systems such as modality and Mood, but they may be 'experientialized,' that is, metaphorically expressed as if they were part of the content. Examples 2 to 5 illustrate the difference.

(2) Perhaps a cable show will make for an easier transition into electoral politics.
(3) It is possible that time changes somehow inside a black hole.
(4) Was he any good?
(5) I'd like to ask whether you really read my article.

In 2, the interpersonal modal disjunct *perhaps* is part of a multiple Theme: it contributes to Theme but does not "exhaust the thematic potential of the clause" (Halliday, 1994: 52). In 3, by contrast, the writer's assessment of probability is construed as if being *possible* were an 'external' attribute of the proposition *time changes somehow inside a black hole*. Similarly, in 4, the ordering Finite^Subject signals that this is an interrogative, functioning as a question; whereas in 5 the speech function being performed is made experientially explicit through the projecting (reporting) clause *I'd like to ask* (see Halliday and Matthiessen, 2004: 626, on interpersonal projection). In such cases, there are three main options in identifying Theme. In 3, for example, Halliday (see, e.g., Halliday and Matthiessen, 2004: 98) identifies *it* alone as Theme (which, for convenience, may be described as 'minimal Theme,' shown by double underlining above), with *time* as the separate subsidiary Theme of the embedded clause. Thompson (2004: 152) argues that the experientialized interpersonal meaning *it is possible* functions as a type of enhanced Theme that he calls 'thematized comment'; and a number of other analysts such as Martin (1995: 251) view *it is possible* as an interpersonal element in a multiple Theme and therefore include the following Subject in Theme ('maximal' Theme, with single underlining). Grammatical metaphor involves a recalibration of the relationship between meaning and form, and the multiple analyses therefore reflect different analytical emphases: Theme will be identified differently depending on whether a more semantically-oriented or a more formally oriented perspective is taken. All three options are therefore justifiable, and provide complementary perspectives; but, in order to simplify matters, in the following discussion I will generally work with maximal Theme.

Theme in Text

Unit of Analysis

Three main units of analysis have been used in investigating Theme in text: the clause, the T-unit (an independent clause and any clauses dependent on it – Hunt, 1965), and the orthographic sentence. Example 6 shows the effect of choosing each of these in turn, using a sentence from extract 1 above:

(6a) When you have a dog, you put in food and attention, and what you get out is unconditional affection and respect.
(6b) When you have a dog, you put in food and attention, and what you get out is unconditional affection and respect.
(6c) When you have a dog, you put in food and attention, and what you get out is unconditional affection and respect.

(In 6b, as noted above, some analysts would take *when you have a dog, you* as the first Theme of the T-unit.) There are different grounds for taking each of these options: the clause is the fundamental linguistic context within which the Theme-Rheme structure operates and thus provides the analytical baseline; the choice of the T-unit highlights the fact that the structural dominance of an independent clause reflects informational dominance and therefore Themes at this level signal more visibly the way a text is unfolding; whereas the sentence is clearly salient for writers as it is orthographically marked off (it is, of course, less relevant to most spoken discourse). The options provide complementary perspectives on thematic choices in text: very broadly, a clause-by-clause analysis tends to highlight continuity of topic, whereas analyses based on the T-unit or sentence tend to bring out more strongly stages in the unfolding of the text. This can be seen clearly in the following extract (taken from a longer extract that will form example 8 below). T-unit Themes (which in this case are identical with sentence Themes) are underlined; clause Themes are in italics.

(7) *When MNEs* are exporting into a foreign market, *host country nationals* will handle everything. *As the firm* begins initial manufacture in that country, *the use of expatriate managers and third country nationals* begins to increase. *As the company* moves through the ensuing stages of internationalization, *the nationality mix of the managers in the overseas unit* continues to change to meet the changing demands of the environment.

Table 1 compares the Themes at T-unit and at clause level. The table brings out the fact that the T-unit Themes signal the chronological stages in the internationalization process, whereas this is obscured in the clause Themes. Instead, these establish two alternating threads of continuity: the MNEs (multinational enterprises) and the different kinds of personnel involved in each stage.

Table 1 Comparison of themes at different levels

T-unit/sentence themes	*Clause themes*
When MNEs are exporting into a foreign market,	When MNEs
As the firm begins initial manufacture in that country,	host country nationals As the firm
As the company moves through the ensuing stages of internationalization,	the use of expatriate managers and third country nationals As the company the nationality mix of the managers in the overseas unit

A full account would clearly need to consider all three options, although, for reasons of space, I will work primarily with T-units in this article.

The Functions of Theme in Text

Much of the work on Theme in text within the Systemic Functional tradition draws inspiration from Fries (1981/1983); and it was in this paper that he suggested that thematic choices across a text reflect the text's 'method of development' – a term that has become probably the most widely used gloss on the function of Theme. A number of different ways of visualizing its function have also been proposed: in a later paper (1993: 338) Fries himself describes Theme as providing "a framework for the interpretation of the clause" and as "orient[ing] the receiver to what is about to be communicated," whereas Martin (1992: 436) characterizes Theme as "scaffolding" the rhetorical structure of a text. Matthiessen talks of it as establishing "a local context" for the clause (1995a: 514), and as signaling the current 'logogenetic growth-point' in the instantial system of the text (1995b: 32) – that is, indicating which aspect of the experiential and/or interpersonal meanings in the text is about to be developed.

Approaches to Thematic Analysis

In order to explore the significance of these glosses more fully, it is necessary to examine thematic choices in text from a variety of perspectives. Three main aspects of Theme in text have been explored: thematic progression, Theme type, and thematic content. These are complementary perspectives, and many studies combine two or all of them; but it is convenient to outline each of them in turn.

Thematic progression, or TP (Daneš, 1974; Dubois, 1987) tracks the source of the content in Theme. Daneš identifies three main patterns of progression: constant, in which the content in one Theme connects (through lexical repetition, pronominalization, etc.) to a preceding Theme (usually although not necessarily immediately preceding); simple linear, in which the Theme connects to a preceding Rheme; and derived, in which successive Themes connect to a 'hyper-Theme' that may or may not be explicitly realized in the text. These categories can be illustrated with the following extract, which is deliberately chosen as an instance of a carefully planned text that is strongly oriented toward experiential concerns. It is taken from a university-level Business Studies textbook (reproduced with permission from A. M. Rugman and R. M. Hodgetts, 1995. *International Business: A strategic management approach*. New York: McGraw-Hill. pp. 324–5). T-unit/sentence Themes are underlined and numbers added for ease of reference; bolding is as in the original.

(8) [1] **International human resource management (IHRM)** is the process of selecting, training, developing, and compensating personnel in overseas positions. [2] This chapter will examine each of these activities. [3] Before doing so, however, it is important to understand the general nature of this overall process, which begins with selecting and hiring.

[4] There are three basic sources of personnel talent that MNEs can tap for positions. [5] One is **home country nationals**, who reside abroad but are citizens of the parent country of the multinational. [6] These individuals are typically called **expatriates**. [7] An example is a U.S. manager assigned to head an R&D department in Tokyo for IBM Japan. [8] A second is **host country nationals**, who are local people hired by the MNE. [9] An example is a British manager working for Ford Motor in London. [10] The last is **third country nationals**, who are citizens of countries other than the one in which the MNE is headquartered or the one in which they are assigned to work by the multinational. [11] An example is a French manager working for Mercedes-Benz in the United States.

[12] Staffing patterns may vary depending on the length of time that the MNE has been operating. [13] Many MNEs will initially rely on home country managers to staff their overseas units, gradually putting more host country nationals into management positions as the firm gains experience. [14] Another approach is to use home country nationals in less developed countries and employ host country nationals in more developed regions. [15] This pattern has been found fairly prevalent amongst U.S. and European MNEs. [16] A third pattern is to put a home country manager in charge of a new operation, but once the unit is up and running, turn it over to a host country manager. [17] Figure 12.1 provides an illustration of the types of

Table 2 Thematic Progression in a Planned Text

[13] Many MNEs will initially rely on home country managers to staff their overseas units, gradually putting more host country nationals into management positions as the firm gains experience.

[14] Another approach is to use home country nationals in less developed countries and employ host country nationals in more developed regions.

[15] This pattern has been found fairly prevalent amongst U.S. and European MNEs.

[16] A third pattern is to put a home country manager in charge of a new operation, but once the unit is up and running, turn it over to a host country manager.

[17] Figure 12.1 provides an illustration of the types of managers, by nationality mix, required over the stages of internationalization.

[18] When MNEs are exporting into a foreign market, host country nationals will handle everything.

[19] As the firm begins initial manufacture in that country, the use of expatriate managers and third country nationals begins to increase.

[20] As the company moves through the ensuing stages of internationalization, the nationality mix of the managers in the overseas unit continues to change to meet the changing demands of the environment.

managers, by nationality mix, required over the stages of internationalization. [18] When MNEs are exporting into a foreign market, host country nationals will handle everything. [19] As the firm begins initial manufacture in that country, the use of expatriate managers and third country nationals begins to increase. [20] As the company moves through the ensuing stages of internationalization, the nationality mix of the managers in the overseas unit continues to change to meet the changing demands of the environment.

In Table 2, the source of each Theme is shown by arrows: dashed arrows show constant TP; dotted arrows show linear TP; and solid arrows show derived TP.

As can be seen, the text relies mainly on derived TP, with occasional examples of linear TP, and one possible case of constant TP (I have taken *an example* in [7] as connecting to *these individuals* in the preceding Theme, but it could equally well connect to the Rheme of [6] or even [5]). There are a number of 'breaks' (Ventola and Mauranen, 1991, label the TP in such cases as 'unmotivated'): in particular, references to the text (*this chapter*, *Figure 12.1*) appear to stand outside 'normal' TP. In addition, I have shown the Theme of [4] as entering into derived TP, connecting to the Rheme of [3]; but existential *there* has no experiential meaning, and the connection is in fact from Rheme to Rheme. As a number of researchers (e.g., Cloran, 1995) have noted, such connections are relatively common but cannot be accounted for within the original TP model.

However, leaving aside these analytical problems, we can consider what the TP patterns reflect about the text. They highlight the fact that the text has a clear and relatively simple hierarchical organization, with successive aspects of the topic introduced in Rheme and elaborated on in one or more following sentences, with the focus of each stage of the elaboration signaled in Theme position: for example, the *three basic sources* mentioned in [4] are thematically listed in [5] *One*, [8] *A second* and [10] *The last*. The general pattern is thus that new topics are brought into the text in the Rheme of sentences which function as hyper-Themes and then shift into Theme until the next topic is introduced. This picture is made more complex by the fact that the patterns tend to overlap: for example, the Theme of [12] connects to the Rheme of [3], showing that it is a new elaboration of *the general nature of this overall process*; but, because [12] is itself a hyper-Theme, the Rheme sets up the topic of the next stretch of text, the way that staffing patterns *may vary* (to which the Themes of [13], [14] and [16] then connect).

So much for the individual text; but it is also interesting to consider to what extent these findings are more generally applicable. Fries (1981/1983) originally hypothesized that patterns of TP would vary according to genre: for example, narratives might be expected to draw fairly regularly on constant TP to maintain focus on a particular character, whereas argumentation would typically be reflected in linear TP, with each step in the argument involving the thematizing of matter in the preceding Rheme. However, he later (1995a: 319) concluded that, despite some evidence of correlation, the relationship is more complex and may be disrupted by local concerns. Extract 8 might at first sight appear to support the hypothesis that derived TP is associated with exposition, in which different aspects of a topic are elaborated on and exemplified; but this appears to be dependent on incidental factors such as the number of examples given. The relationship between [8] and [9], and between [10] and [11], is also one of elaboration; but as only one example is given in each case, these are categorized as linear TP.

The identification of the source of thematic content in terms of TP is therefore useful in tracking the flow of information through a text; but the ways in which it may correlate with other aspects of textuality remain somewhat unclear. There is also the restriction that 'content' in TP is seen in purely experiential terms, which means that it can be difficult to handle thematized interpersonal meanings: these may appear to represent breaks even though the text is clearly unfolding coherently.

We now turn to the second approach to analysis, Theme type, which focuses on whether Themes are simple or multiple, and whether they are unmarked, marked, or enhanced. The same extract can be used to illustrate this approach. Table 3 shows the Themes arranged by type ('maximal' Themes following marked Theme are in italics).

It is immediately noticeable that there are no textual or interpersonal Themes (except *however* in the maximal Theme analysis of [3]); and, of course, the absence of features is as significant as the presence. There are in fact textual signals, which will be discussed below; but it is clear that the writers are not much concerned to negotiate interpersonal relationships with the reader: the relative statuses are construed as more or less fixed, and the focus is on the transmission of information. This is also reflected in the absence of enhanced Theme (again with the exception of maximal Theme in [3]). Enhanced Themes appear to be associated with greater rhetorical effort (Francis, 1990), and the avoiding of such effort contributes to the authoritative, factual tone of the extract.

[20]	As the company moves through the ensuing stages of internationalization,		*the nationality mix of the managers in the overseas unit*

The majority of Themes are unmarked, reflecting the maintenance of focus on aspects of a single main topic. The first marked Theme is in [3]: it 'places' this first main topic by signalling that it is merely a preliminary (albeit an *important* one) to the central topic of the chapter (examining each of the activities listed in [1]), which will follow later. This helps to explain why the Theme of [3] stands out: it functions at a relatively high level to signal the organization of the chapter. It has often been argued (e.g., by Fries, 1995a) that marked Themes are typically associated with changes in the direction of a text: they establish a new local context, in contrast to unmarked Themes that typically reflect continuity of topic. This applies very clearly to [3] – and it is worth noting that the maximal Theme analysis picks up further contextualization in the enhanced Theme, in terms of the writers' evaluation of the information they are about to give: there is noticeable thematic 'turbulence' at this point in the text. The other marked Themes, in [18]–[20], work at a lower level in the textual hierarchy; but they illustrate the same principle as [3] – see discussion of Table 1 above.

There is a good deal of evidence that the different functions of marked and unmarked Themes discussed in relation to this particular extract apply more generally across a range of genres (Downing, 1991; Martin, 1992); and Davies (1997) makes the stronger claim that different genres display different patterns of marked and unmarked Themes. By contrast, Fries (1981/1983) notes that the distinction does not apply to the way in which Themes reflect the method of development in the texts he uses to illustrate his argument: the relevant experiential content appears apparently indiscriminately in both marked and unmarked Themes. As with TP, the picture is therefore more complex than it appears at first.

The final approach to analysis, thematic content, categorizes the type of meanings found in Theme, along various dimensions. Probably the most widely used type of categorization is in terms of the entities that are thematized. This may involve general classes such as concrete vs. abstract, or 'real-world' vs. 'virtual' entities ('virtual' entities are those construed by grammatical metaphor, such as *comparison* or *categorisation*, or by embedded propositions treated as entities – for example, to lose one parent *may be regarded as a misfortune*), or specific sets of classes relating to the topic of the text(s) being analyzed. Gosden (1993), for example, identifies four domains from which Subjects (which he treats as obligatorily thematic) in academic research articles may be

selected: Participant (the writer, other researchers, etc.); Discourse (the text itself); Hypothesized and Objectivized (a somewhat disparate category covering phenomena such as evaluation and abstract concepts); and Real-World (concrete entities). He argues that these are specific to the genre he investigates, and, furthermore, that the distribution of choices from the four domains varies according to the different generic stages of the research article. Berry (1995: 58) draws an important distinction between informational or topic-based Themes and interactional Themes (those which refer to the writer/speaker and reader/hearer), and she discusses the effect of writers choosing different patterns of choices between these two categories.

Table 3 shows that in extract 8 there are no interactional Themes: at the point at which one might most easily have appeared, in [2], the writers opt to foreground their text – *this chapter* – rather than themselves. A number of the informational Themes pick out entities such as *sources* and *patterns* that are semitechnical terms intermediate between 'concrete' and 'abstract.' Concrete (although nonspecific) entities such as *many MNEs* also occur, but not very frequently: the writers are framing the information in terms of generalized concepts, with the concrete entities more typically appearing in Rheme. The usual movement within each T-unit is thus from thematized class to rhematized exponent.

The other significant group of thematized entities relate to the textual organisation. I mentioned above that there are few, if any, textual elements in Theme; but the organization is, in fact, signaled thematically at times, through experientialized forms rather than through textual Adjuncts: rather than *for example*, the writers use *an example [is]*, and rather than *thirdly*, they use *a third pattern [is]*. This means that the organization is construed as inherent in the information: the reader of this textbook is being firmly steered towards assimilating the relationships (mostly elaboration, as noted above) between the chunks of information along with the content itself. This reinforces the tendency to move within the T-unit from concept to realization: the concrete details are consistently presented in the frame of what Thompson (2004: 167) calls the 'conceptual map' of the text. It is certainly no accident that it would be very easy to 'translate' the extract into note form with the categories and relationships taken from the thematic content – Table 4 illustrates this for sentences [4]–[11]. The information to be placed under each heading within the framework is taken from the Rhemes.

This mapping of thematic content onto the framework and of rhematic content onto the 'filling' is typical of planned, expository text (see Fries, 1981/1983, and Thompson, 2004, for similar examples),

Table 4 From theme to notes in a textbook

Three basic sources of personnel talent:	
[5]	source 1:
[7]	e.g.
[8]	source 2:
[9]	e.g.
[10]	source 3:
[11]	e.g.

and illustrates the claim (made with precise caution in Fries, 1995b: 9) that where a text has a clear method of development it will be reflected in the Theme choices, particularly in terms of thematic content. However, as Fries makes clear, not all texts have a simple method of development, and it cannot be expected that the functions of Theme in texts such as 8 will necessarily apply to all texts.

Theme Patterns in Unplanned Text

In order to round out the reasonably clear but partial picture that has emerged so far, therefore, it is necessary to explore Theme in a different text type. The ways in which Theme works in text appear to be influenced by two main intersecting factors: the degree to which the text is planned or unplanned, and the degree to which it is experientially or interpersonally oriented (Matthiessen, 1995b; Martin, 1995). The following outline will, more briefly, revisit the approaches to Theme analysis introduced above, using a text at the other extreme of these clines in order to illustrate some of the differences.

The text (transcribed by Angela Reid) is an extract from 'a television chat show (extract from *Trisha*, June 2001, produced by ITV Anglia Television, reproduced with permission)' dealing with personal problems: the situation of the 'guest' is described and then the audience are invited to put questions and give comments. T is the host, S the guest, and A1-2 are members of the audience. In Table 5, T-unit Themes are underlined, and TP is shown using the same conventions as in Table 2 above.

TP has mainly been used to analyze monologic texts, and Table 5 illustrates some of the difficulties of applying it to dialogue. Some of the gaps could be filled in if elliptical material were somehow reinstated (e.g., [22]–[23]); but the discourse is clearly more loosely structured than extract 8, not least because new speakers may not connect back in any obvious way to what the previous speaker has said. Where TP can be traced, there is generally reliance on constant TP (e.g., [4]–[5]), though often this involves jumping over one or more intermediate T-units either within a turn (e.g., [5]–[7]) or across turns (e.g., [9]–[11]). It also involves allowing links between *I* and *you* in

Table 5 Theme and thematic progression in an unplanned, interpersonally oriented text

T: [1] let me ask you Sally if the fact that he went means that *he* failed your test

S: [2] yes he did

T: [3] yes

A1: [4] I feel that Sally's actually setting *him* up a bit

[5] because the thing that seems to me is that Sally's going out to work

[6] he's unemployed

[7] and she *feels*

[8] he's frittering away his time at home when he should be out there earning money the same as she is

T: [9] is that it

A1: [10] I feel that she's pushing him away

T: [11] thank you but is that *how you feel* Sally

S: [12] I feel as if I'*m the sole earner*

[13] and well it should be equal

[14] and I'm working all day

[15] and he's free to do anything

T: [16] but what about these mood swings throwing things all that sort of thing

S: [17] he *gets me so annoyed*

[18] he doesn't understand where I'm coming from

T: [19] can I ask why Sally

S: [20] I don't trust him

T: [21] you don't trust him

S: [22] no

T: [23] ok

[24] yes

A2: [25] you know you're planning marriage

S: [26] yeah

A2: [27] are you going to base the *marriage* on distrust and paranoia

[28] because it's never going to work

[29] and you're better to part and find partners you can trust

utterances by different speakers (e.g., [20]–[21]), on the grounds that the entity referred to is the same. The predominance of constant TP reflects the broad maintenance of focus on the two main people involved, Sally and her boyfriend: each move forward in the discourse is related not to developing aspects of some overarching topic (as with the derived TP in 8) but to discussing different actions and feelings of these two people. To some extent, this therefore bears out the hypothesis that the patterns of TP may vary with type of expansion and perhaps with genre; but it suggests more strongly that the concept of TP is only sporadically applicable to certain types of discourse (which in itself may, of course, be a distinguishing feature of those discourses).

Table 6 shows the Theme choices in the conversation, laid out as closely as possible to Table 3, to allow easy comparison.

What immediately stands out is the much more extensive use than in extract 8 of multiple and enhanced Theme. The latter are all experientialized interpersonal meanings, and, together with the frequent interpersonal Themes, they construe the conversation as being about negotiation over opinions as much as content. This is unsurprising in human terms, because the situation is inherently face-threatening for Sally: her private life is (with her collaboration, of course) being discussed in public. In addition, this is dialogic discourse, and many of the interpersonal Themes reflect the exchange of turns: for example, 'response' words such as *yes* in [2] and *no* in [22], and the Finite as interpersonal Theme in interrogatives such as [8] (see Halliday and Matthiessen, 2004: 81, for the basis for this analysis). Two of the enhanced Themes ([1] and [19]) in fact construe awareness of both the addressee's needs and the current state of the ongoing discourse: the host enacts her control over the conversation through showing politeness by asking permission (*let me, can I*) and signaling the speech function being performed (*ask you if, ask why*). The relationships between addressers and addressees are much less settled than in the textbook; and the majority of the negotiation over the right to speak, viewpoint, etc. is done in the thematic zone; the Rhemes are where the content is mainly expressed. The framing of the discourse is therefore primarily in terms of interpersonal concerns; and the 'filling' realizes the experiential concerns.

Table 6 Theme type in an unplanned, interpersonally oriented text

Textual theme	*Interpersonal theme*	*Experiential theme*		
		Marked theme	*Enhanced theme*	*Unmarked theme*
[1]			let me ask you Sally if	*the fact that he went*
[2]	yes			
[3]	yes			he
[4]			I feel that	*Sally*
[5] because			the thing that seems to me is that	*Sally*
[6]				he
[7] and				she
[8]	is			that
[9]			I feel that	*she*
[10]	thank you			
[11] but	is			that
[12]			I feel as if	*I*
[13] and well				it
[14] and				I
[15] and				he
[16] but	[what about]			what about
[17]				he
[18]				he
[19]	[*why*]		can I ask	*why*
[20]				I
[21]				you
[22]	no			
[23]	ok			
[24]	yes			
[25]	you know			you
[26]	yeah			
[27]	are			you
[28] because				it
[29] and				you

This is reinforced by the thematic content. If we focus on the unmarked Themes, a number are interactional Themes (Berry, 1995) – e.g., *I* in [14], *you* in [27]; and in this context *she* and *Sally* can be included as at least semi-interactional, as the speaker is directing his comments at Sally via the host. Thus, the interpersonal orientation permeates all parts of the thematic zone. In addition, with the exception of [1], the Themes are very short: they have much less content than the Themes in the textbook. They are also predominantly pronouns, referring either to the people involved or to previous messages (*that* in [8] and [11]). The speaker is not, therefore, using Theme to introduce new topics or to signal new points of departure. The overall effect is that the unmarked Themes do much less of the communicative work than in extract 8; the informational 'weight' is in the interpersonal and enhanced Themes and the Rhemes.

One general way of viewing the differences between Theme patterns in the textbook and conversation extracts is to see them in terms of competition for thematic space between various kinds of experiential and interpersonal concerns. It is in fact predictable that this competition will arise, since, as Matthiessen (1995b) points out, Theme (together with other textual phenomena) functions as an 'enabling resource' for both experiential and interpersonal meanings.

Conclusion

There has only been space in this article to examine Theme in two extracts, but the discussion has been designed to show that concepts such as 'method of development' and 'scaffolding' need to be interpreted rather differently in different types of text, with the degree of planning and the orientation to experiential or interpersonal meanings as the crucial dimensions of difference. Registers that fall somewhere between the two extremes illustrated here along either of these dimensions have been shown (e.g., by Francis, 1990; Fries, 1995a; Davies, 1997) to vary systematically in the way that their thematic choices function. For example, persuasive and argumentative texts such as newspaper opinion columns or academic research articles (especially in 'softer' disciplines) are highly planned but address interpersonal concerns more than a purely expository text such as 8; and this is reflected in the way in which the Themes scaffold the rhetorical unfolding of the text (Martin, 1995; Matthiessen, 1995b). A further complicating factor, which it has not been possible to explore here, is the degree of sophistication aimed for: there is a tendency for more 'unsophisticated' written texts (e.g., textbooks for children) to display relatively simple, clear patterns of thematic choice, whereas greater complexity of argument or exposition can be construed by more complicated interweavings of thematic patterns. The effects of these different factors make it difficult to arrive at a simple description of the function of Theme in text: it is useful, rather, to invoke Wittgenstein's analogy of family resemblance and to see thematic choice as broadly working to provide a textual framework of some kind, but with the type of framework varying according to the register.

Defining 'Thesaurus'

The term 'thesaurus' has undergone several extensions in meaning over the years, so that today it can cover at least three different senses: (1) 'special word-list' or 'lexicon,' (2) 'semantic dictionary' or 'nomenclator,' and (3) 'terminological database' or 'index.'

The first of these, the traditional and now largely obsolete sense of 'classical lexicon' (regarded as a 'treasury' of words) is associated with early historical or literary dictionary projects, such as Thomas Cooper's *Thesaurus Linguae Romanae et Britannicae* (1565), the *Thesaurus Lingae Latinae* (10 volumes published since 1894; incomplete), the *Trésor de la langue française* (1971–1994) and author concordances such as the *Shakespeare Thesaurus* (Marvin Spevak, 1993). The second and nowadays most central sense of 'semantically organized dictionary' has been gaining ground since the middle of the 19th century, when Peter Mark Roget, a medical doctor whose family had come to Britain from France and who had developed a life-long interest in scientific taxonomies, developed his famous *Thesaurus of English words and phrases* as a conceptually structured word-finder. The third and most recent sense of 'index to the vocabulary' of specific fields is relevant in the study and codification of technical terminology and information retrieval, e.g., Sharon Black's *Thesaurus of subject headings for television* (1989) and Alvin Walker's *Thesaurus of psychological index terms* (8th edn., 1997).

The rest of this article concentrates on the most relevant second meaning, which has been defined as "a linguistically oriented wordbook in which general-language vocabulary is organized from a semantic point of view" (Margaret Rogers, as cited by Dušan Gabrovšek, 1997: 188), designed to give guidance on alternative words for similar concepts. The definitions above already illustrate the problem which thesauruses address: how to explain and express ideas which are couched in words with multiple meanings (such as the polysemous lexeme *thesaurus* itself) by means of semantically related words (such as the partial synonyms *word-list*, *reference book*, *lexicon*, *glossary,* and *index*). Another example of a lexical field that illustrates the nature, development, and roles of the thesaurus is the group of vocabulary items that can communicate the concept of 'comfortable seat for more than one person,' such as *sofa*, *couch, settee*, *divan,* and so on.

The Thesaurus in Dictionary Research

The study of thesauruses is still a relatively neglected field, and no single item in the literature on dictionary

The Thesaurus in Dictionary Research

The study of thesauruses is still a relatively neglected field, and no single item in the literature on dictionary

research or metalexicography covers all aspects of the subject. The most important authority is the German linguist Werner Hüllen, who convened one of the first conferences on thesaurus lexicography (1994), wrote books on English lexicography and Roget's *Thesaurus* (1999, 2004), and commissioned a special issue of a journal on the theme of thesauruses and other onomasiological dictionaries (Hüllen, 2006). The only other specialist conference on this topic, the 5th NLRI Symposium in Tokyo (Nakano *et al.*, 1997), provided an overview of thesaurus lexicography for Asian languages such as Japanese, Chinese, Korean, and Hindi in comparison with English.

The distinction between 'semasiology' (or sign interpretation) and 'onomasiology' (or name allocation) is often claimed to be relevant, as it can help us understand the essence of thesaurus lexicography. The traditional general monolingual dictionary is semasiological in the sense that it provides an explanation of the meaning(s) of a given word by means of definitions or examples, the direction being from word to meaning – for the purpose of helping native speakers with passive 'decoding' or comprehension of utterances. More specialized onomasiological dictionaries such as thesauruses, on the other hand, start with a given concept or meaning and provide a range of lexical choices for expressing that concept, the direction being from meaning to word – for the purpose of assisting with active 'encoding' or composition of discourse.

There are many different ways of studying the intricacies of thesauruses. The most important of these will be discussed here in terms of six 'perspectives' that have been explored in dictionary research (Hartmann, 2003):

1. Dictionary history
2. Dictionary criticism
3. Dictionary typology
4. Dictionary structure
5. Dictionary use
6. Dictionary IT

The first of these research perspectives is 'dictionary history.' Several aspects of anthropological, cultural, and personal history can be shown to be relevant. Of these, the most important in this context is the so-called genre-specific approach, aimed at finding out how different types of dictionaries have evolved for different purposes.

The onomasiological tradition in lexicography is long-established, but more recently it has been outclassed and overshadowed by semasiology, with thesauruses, synonym dictionaries and even nonlexicographic reference products such as usage guides, crossword puzzle solvers, and plant identification books coming under the universal spell of the alphabet as the most convenient device for arranging the information. Since it became a subject worthy of scholarly attention, dictionary history has thus been primarily the story of A–Z wordbooks, while the topical-semantic approaches have only rarely been explored systematically, e.g., by Igor Burkhanov (1999), who investigated the links between linguistic semantics and dictionary structure under the heading 'ideography,' and Werner Hüllen, whose two monographs summarized what was known about the history of early English dictionaries as thematically arranged pedagogical reference books (Hüllen, 1999) and about the origin and impact of Roget's *Thesaurus* (Hüllen, 2004).

Roget is usually shown as inheriting the tradition of (French) synonym dictionaries and adapting it in a completely new medium, the thematically presented (English) thesaurus, by means of systematically arranged taxonomic clusters, e.g., 'couches and sofas' would be treated within the class 'the home' and the subclass 'furniture'. The technical term 'cumulative' has evolved to characterize such dictionaries, with lists of words as alternatives to the headword, which do not always help even native speakers to know exactly what distinguishes, say, a couch from a 'sofa'. This is in contrast to 'distinctive' works such as Tom McArthur's *Longman Lexicon* (1981), which provides foreign learners with explanatory discriminations, by definition and/or example, for each sense of the words listed: for instance, for the five specific nouns in the subclass 'couches and divans' within the class 'buildings, houses, the home, clothes, belongings, and personal care,' some even with pictorial illustrations, and in some editions with foreign-language equivalents.

Some early synonym dictionaries attempted to discriminate the individual members of such conceptually related groups of words, but more recent products, under the influence of Roget's *Thesaurus*, tend to merely enumerate them. Sometimes, however, the boundary between a semasiological dictionary and an onomasiological thesaurus is deliberately blurred, e.g., in the French tradition by the so-called 'analogical' dictionary (Hausmann, 1990), or in the English tradition by the increasingly popular 'dictionary and thesaurus' hybrid, especially since it has become relatively easy to combine the two genres electronically (see below).

Table 1 shows that Roget's pioneering *Thesaurus* continued well beyond the author's death in 1869. While it was commercially successful and influential, sparking off many imitations both within British and American English and in other languages (see the next section below, on thesauruses in specific languages),

Table 1 The story of Roget's Thesaurus

its cumulative pattern has not fully replaced the earlier tradition of distinctive synonym dictionaries, and no single design format dominates the genre today.

In the first few years, the annual reprints (some indicated in parentheses) were called 'editions,' although they were identical impressions. More recent editions, both in the United Kingdom and in the United States, have differed more substantially, with revising editors leaving their individual marks on them, attempting to update the classifications that reflect the various underlying philosophical, religious, and scientific traditions. In general, American editions have tended to 'humanize' the overall word list, by spreading out the top-down arrangement of notional categories (from 'abstract relations,' 'space,' 'matter,' and 'intellect,' to 'volition' and 'affections') and placing greater emphasis on everyday folk concepts (from 'body,' 'feelings,' 'place,' and 'living things' to 'sports,' 'mind,' and 'technology'); they have also introduced more encyclopedic material, made the alphabetic principle more dominating, and provided more distinctive (sometimes definitional) information (Piotrowski, 1994; Burkhanov, 1999).

The question of why it can be relatively difficult to find meaningful links between *sofa*, *settee*, *couch*, and their potential synonyms in thesauruses is part of the concern of 'dictionary criticism,' the second perspective of dictionary research, which in spite of a relatively long tradition is still underdeveloped, especially in the way that one or more dictionaries are reviewed in the popular press or in scholarly journals. Most English-language thesauruses that an average user is likely to consult, provide lists of near-synonyms in no particular or apparent order, without telling those who want to know what exactly the differences are between a *couch*, a *sofa* and a *settee*; how a *loveseat* can bridge the gap between an upholstered armchair for one and a soft seat for more than one; where the borderlines are between a relatively soft *sofa* and a relatively hard *settle*; or a *sofa* for sitting on and a *sofa bed* for sleeping on; and how many different subtypes (e.g., *chesterfield, davenport*, *ottoman*) might be distinguished.

No universally agreed-upon criteria have been established yet for the evaluation of reference works, and this sad fact is particularly true of thesauruses. The few studies that have been attempted have led authorities to diagnose a general crisis among contemporary compilers, publishers, and critics of such works of reference, while at the same time marveling at their continuing high sales figures. Dictionary-buying guides (such as Loughridge, 1990) do provide limited information on existing products, but usually without covering all the issues.

As for the third perspective of relevance here, 'dictionary typology,' the Russian linguist and lexicographer Lev Vladimirovich Shcherba (1941/1995/2003) introduced the term 'ideological' dictionary, in contrast to the 'ordinary' or conventional defining/translating dictionary. This is one of six oppositions by which he set the precedent for many more bipolar distinctions, such as orthographic/ideographic, semasiological/onomasiological, alphabetic/ thematic, word-based lexical/thing-based encyclopedic, definitional/conceptual, syntagmatic/paradigmatic, explanatory/terminological, and so on, that have subsequently characterized the literature on classifying dictionaries. Many authors unfortunately have ignored the significance and complexities of purpose or function. The typology of onomasiologial dictionaries will remain in the doldrums

Table 2 Subtypes of the thesaurus genre

Exemplar	*Year of publication*	*Macrostructure*	*Microstructure*
P. M. Roget comp *Thesaurus of English Words and Phrases*	1852	thematic/alph. index	cumulative
R. Soule comp. *A Dictionary of English Synonymes . . .*	1871	alphabetic	cumulative

until dictionary researchers realize the diversity of existing subtypes or genres, from nomenclators, onomastica, and promptoria, to terminological glossaries, usage guides, and vocabulary builders, together with the manifold educational, technological, social, and other factors that ought to be considered in their classification.

Table 2 illustrates the fact that even within the thesaurus genre there are considerable variations, and several subtypes of print and electronic dictionaries can be distinguished according to whether the organization of the word list (macrostructure) is thematic or alphabetic, and whether the presentation of information inside the entry (microstructure) is distinctive or cumulative, sometimes in combination (see also Table 3 for Oxford University Press products). Some thesauruses can be bilingual; some can be limited to certain social or literary varieties of the language; some can be dedicated to a particular historical period of the language. (For a thesaurus-type treatment of the vocabulary of technical fields, *see* **Terminology and Terminological Databases**.)

The fourth perspective, 'dictionary structure,' might help us explain the often arbitrary and indiscriminate treatment of *sofa* and its synonyms in thesauruses like Roget's and its adaptations in other languages, e.g., in terms of such design features as taxonomic word lists and cumulative entries. There are many other aspects of this structural perspective to be considered, and many of the associated controversies are still unsettled, notably which of the currently available systems of semantic theory might be most suitable, and whether and how all this could be supported by electronic techniques (see the section on interdisciplinary aspects below).

Structurally, the distinction between thematic and alphabetic reference works partly overlaps with that between the cumulative and distinctive styles of presentation. Thus, our lexical field of comfortable seating objects could be treated in terms of semantic categories such as conceptual domains (e.g., 'space'), classes (e.g., 'home'), subclasses (e.g., 'furniture') and notions (e.g., 'cushioned seat'). The categories, classes, notions and concepts are sometimes specified in terms of superordinate/hyperonymous lexemes (such as *sofa*), synonymous/heteronymous lexemes (such as *couch*, *settee*, and *divan*) and subordinate/hyponymous lexemes (such as *leather sofa*, *upholstered sofa*, and *chaise longue*). Antonymy, meronymy, and other sense relations are also often displayed. The

lexemes used for this purpose may or may not be prototypical words, or form part of commonsense folk taxonomies or technical terminological systems. The taxonomic levels are sometimes correlated either with traditional divisions like book, chapter, section, and paragraph, or metalexicographic divisions like macrostructure, mesostructure and microstructure (see Figure 1).

Typically, an alphabetic index is required in order to help the lexicographer to place and the user to find the appropriate entry where the lexical field in question may be treated. Alternatively, an alphabetic, rather than ontological, format may be easier from the point of view of access, but it imposes on the lexicographer an even greater burden of sense discrimination. Figure 1 illustrates this, by reference to the most recent American edition of Roget's *Thesaurus*. Category 229 'Furniture' (between 228 'Abode, Habitat' and 230 'Town, City') is a subclass of Class 3 'Place and Change of Place,' while Category 901 'Support' comes between 900 'Counteraction' and 902 'Impulse, Impact' under Class 14 'The Mind and Ideas.' Note that, the various synonyms for individual pieces of furniture for sitting or lying on are listed, but not distinguished, which would make its use by nonnative speakers very difficult.

The relative advantages and disadvantages of structural features certainly affect the fifth research perspective, 'dictionary use,' and the way in which specific reference needs of the user may (or may not) be met by the activation of required reference skills. Why, where, and how would someone seeking onomasiological information of the type sketched above go about finding it? Unfortunately, not much empirical user research has been done in this area, with Ulrich Püschel (1986: 223) complaining that such dictionaries "cannot at all serve the purposes promised by the authors" (quoted from the English abstract), and Herbert Ernst Wiegand (1994) querying whether and how dictionaries of the cumulative genre can possibly be used to solve 'word-finding' problems. What indeed are these purposes and problems, and how do they differ by the nature, age and expertise of users; e.g., in what ways are the needs of foreign learners different from those of native speakers, and how, in any case, is the average user to know which thesaurus to choose in the first place?

229 FURNITURE

Figure 1 Two typical thesaurus entries (from *Roget's international thesaurus* 6th edn., 2001).

One important dichotomy that these doubts have added to the debate is that between (passive) decoding and (active) encoding, the former associated with activities like reading comprehension, and the latter with the writing skills required for text composition and translation. As we have seen, decoding correlates with the traditional (semasiological) dictionary for reception, while for encoding activities, a productive (onomasiological) thesaurus is claimed to be more appropriate. A few years ago, a working party of the so-called Thematic Network Project in the Area of Languages (Hartmann, 1999) surveyed the evidence for relatively low dictionary awareness in university institutions throughout the European Union, including the fact that users failed to admit problems in their reference experience, and received little training in school and even less assistance in bookshops and libraries, least of all for onomasiological dictionaries such as thesauruses.

The sixth research perspective we need to explore is 'dictionary IT,' or using the possibilities of the still new computer media to overcome at least some of the above limitations. One such innovation is the design of 'hybrid' products combining features of the dictionary and the thesaurus (Calzolari, 1988). There have also been experiments combining monolingual and interlingual dictionaries ('bilingualized' reference works), or the dictionary and the often pictorially supported encyclopedia. Computer technology has also brought new benefits in terms of the relative ease of online searches for dictionary users and improved access to corpus evidence for lexicographers.

Thus, from his or her work-station anyone can, through the thesaurus built into its word-processing program, check the lexical field of *sofa* via hypernyms or synonyms, such as *furniture*, *seat*, and *settee*; can search, through the Internet, for lists of bibliographical references (e.g., for the literature on 'onomasiological dictionaries') or for relevant websites (e.g., of libraries and publishers); consult online dictionaries and databases such as *WordSearch* or *Visual Thesaurus* which display synonymous relationships (e.g., for lexical fields like the one around *sofa* in the form of word lists or semantic constellation diagrams); and they can even try to find a way into text corpora and semantic databases such as FrameNet, in which a particular word or phrase may be documented in its respective discourse contexts. It is likely that these developments could also bring improvements to the way semantic information will be collected and presented in future.

Thesauruses in Specific Languages

There is no single publication dedicated entirely to the discussion of thesauruses in English, but in terms of production, marketing, and use, English thesauruses can definitely be said to lead the field: for the period between 1900 to 2000, a recent survey (Hartmann, 2006) located 158 relevant titles, not counting electronic products, published largely in Britain and the United States and a small proportion in other countries (see Tables 2 and 3).

There is an exciting and still largely unexplored wealth of types and subtypes of reference works, from the (early) interlingual/thematic to the monolingual/alphabetic, with a very small proportion that are pedagogically oriented and bilingual. There is also a general tendency today to restyle older synonym dictionaries as 'thesauruses' (occasionally other titles appear, especially for American English, e.g., *wordfinder*, *word menu*, *descriptionary*, and *reverse dictionary*), even though that may make them more cumulative. This is a trend which dictionary publishers are trying at the same time to counteract by producing a new generation of dictionary–thesaurus hybrids. All this is of course part of the pressure of commercial competition, often resulting "in a preference for hiring editorial assistants to update existing successful products rather than inviting established authorities to produce something completely original" (Hartmann, 2006).

Table 3 illustrates the whole range of thesaurus-type reference books offered by one important British dictionary publisher.

The following thesaurus subtypes are represented:

1. Pure 'thesauruses' (up to seven issued, from the large/comprehensive, e.g., *New Oxford thesaurus of English*, to the mini);
2. Dictionary–thesaurus hybrids (up to six, again from fairly large, e.g., *Oxford dictionary, thesaurus, and wordpower guide*, to mini);
3. Special-purpose thesauruses for native-speakers (for up to six age levels of school pupils, e.g., *Oxford school thesaurus*, and foreign learners of English, e.g., *Oxford learner's wordfinder dictionary*);
4. Dictionaries of synonyms, idioms, paronyms, and pictorial dictionaries (e.g., the quadrilingual *Oxford visual dictionary*);
5. Electronic products (e.g., the *Oxford advanced learners' dictionary*, recently also available in CD *Genie* format), which allow the user to click-search definitional, collocational, synonym, and other information, even during word-processing and emailing activities).

For other languages, less variety and less information is available. Table 4 is intended to give an impression of the range of thesaurus-type dictionaries in a number of European languages.

The apparent correlation between the number of speakers of these languages and the number of onomasiological reference works produced for them may not be an accident, but a reflection of the willingness of compilers and publishers to meet the demand for such dictionaries. In some of these, Roget's thesaurus approach has been copied and adapted, while in others, the format of the (distinctive) synonym dictionary prevails. Thus, for German, the comprehensive historical survey by Marion Hahn (2002) documents both the distinctive and the cumulative traditions, the latter including Franz Dornseiff's thesaurus *Deutscher Wortschatz nach Sachgruppen*, recently revised in a new edition. The French 'analogical' pattern, an attempt to combine both traditions, has also influenced practices in other Romance languages such as Spanish, while the Russian approach to thesaurus lexicography has affected those in other Slavonic languages such as Polish. The best comparative treatment to this day remains Carla Marello's encyclopedia article (1990) which described thesauruses in several traditions, going back to the very first printed dictionary in Europe, the pragmatically

Table 4 *Onomasiological Dictionaries in Selected European Languages* (Published During 20th Century)

Language	*Number of speakers (in Europe)*	*Onomasiological dictionaries*	*Number of these in thesaurus genre*	*Representative thesauruses (or synonym lexicons)*
English	57 million	158	70+	Roget's *Thesaurus* [see Tables 1, and 2, Figure 1]
Spanish	39 million	218	100+	J. Casares *Diccionario ideológico* 1942/1995
German	96 million	102	30+	F. Dornseiff *Dt. Wortschatz nach Sachgruppen* 1933/2004
Russian	115 million	45	8	J. D. Apresjan *et al. Novyj ob. slovar' sinonimov* . . . 1997
French	55 million	65	10	D. Péchoin *Thesaurus Larousse: des idées aux mots* 1991
Italian	60 million	26	3	N. Tommaseo *Nuovo dizionario dei sinonimi* 1905/1974
Polish	37 million	25	3	S. Skorupka *Slownik wyrazów bliskoznacznych* 1957/2001
Dutch	22 million	19	5	L. Brouwers *Het juiste woord* 1928/1989
Greek	12 million	8	2	T. Vostantzoglou *Antilexikon i onomastikon* 1949/1990

structured, bilingual Venetian–German travel guide *Introito e porta* of 1477.

Outside Europe, the thesaurus has also flourished. In many ancient cultures, particularly in the Middle East and the Far East, thematic–topical dictionary-making is older than alphabetic lexicography, e.g., in the form of the Chinese thesaurus *Erya*, produced in the 3rd century B.C. Building on the tradition of the Sanskrit thesaurus *Amar Kosh*, by the 6th-century scholar Amar Singh, Arvind Kumar (1998) described work on his *Samantar Kosh*, published in 1996, on the basis of a new logical order of the concepts of Modern Hindi. For Modern Arabic, a new thesaurus (*Kanz al-lughah al-arabiyyah* by Hanna Ghalib) was issued (Librairie du Liban) in 2003. For Afrikaans, the *Groot Tesourus van Afrikaans* by L. G. De Stadler was published (Southern Publishers) in 1994. For Japanese, a range of products are available, including the electronic version of the research-oriented *Bunrui Goi Hyou*, first developed in the 1960s at the National Language Research Institute (and also translated into Korean).

Interdisciplinary Aspects

The field of onomasiology lies right between lexicography and linguistics, since it is concerned with the problem of 'meaning' and its treatment in the dictionary, both in terms of intralingual sense relations between vocabulary items within a language, and of interlingual equivalence relations between vocabulary items in two or more languages. It is not surprising, then, that the linguistic disciplines of semantics and lexicology, as well as the whole of lexicography, have claimed this important territory, in order to understand, model, and improve the presentation of sense relations, for the benefit of native speakers and foreign learners. Various theories and models have been proposed for describing such lexical properties (componential analysis, lexical fields, frame semantics, and prototype semantics), and various reference works have tried to codify their essential features (nomenclators, promptoria, usage guides, and vocabulary builders), none with fully satisfactory completeness.

One recurring example is the domain of *seats* (*chair*, *bench*, *couch*, *sofa*, etc.), which has been investigated, decomposed, and tabulated by structural, anthropological, and cognitive linguists (for example, Helmut Gipper, Bernard Pottier, Charles Fillmore, Anna Wierzbicka, and Igor Burkhanov), and referred to by the (meta-)lexicographer Piet van Sterkenburg (1992: 524) as an "evergreen from structuralism." But long before all this tentative modelling in linguistic semantics, lexicographers from Girard to Roget had to cope with the notion of overlapping meanings in their synonym dictionaries and thesauruses. The history of Roget's *Thesaurus* and some of his predecessors, contemporaries, and successors has been documented by Werner Hüllen (2004), but a comparative study of such dictionaries in various languages is still outstanding.

A number of observations can be made on the development and nature of such onomasiological reference works. Most are monolingual, but for the more popular languages, bilingual synonym dictionaries exist, too; there is even a polyglot comparative *Dictionary of selected synonyms in the principal Indo–European languages* by Carl D. Buck (1949), which dealt with the lexical field of 'seats' in terms of one entry, *chair* (within the notion 'Dwelling, House, Furniture,' between *bed* and *table*), listing its equivalents in Greek, Latin, French, English, German, and 20 other languages. However, the comment on those selected says that "not included are words which may denote any kind of 'seat. . . .'"

During the last few years, there has been a convergence of such disciplines as (case) grammar and (frame) semantics, both within 'cognitive' linguistics and in relation to lexicography (and metalexicography), all supported by IT. Thus, the development of WordNet, a psycholinguistically inspired lexicon of semantic associations which specifies synonyms, hypernyms, hyponyms, holonyms, meronyms, and other coordinate terms for most of the more frequent vocabulary items in English, together with FrameNet, another American approach to computer-assisted semantic analysis, have made lexicographers aware of the advantages of corpus linguistics and the potential benefits of displaying semantic networks such as the 'concept lattices' shown in Figure 2.

The synonym cluster associated with the word *couch* is shown here, first as a verb with the meaning 'to formulate,' leading on to at least three possible synonyms (*put*, *frame*, and *cast*), and then as a noun with several distinct meanings, one of which

Figure 2 A synonym network (based on the *Visual thesaurus*) www.visualthesaurus.com, published by Plumb Design (1998–2004) as an electronic adaptation of *WordNet*, developed at Princeton University by Miller *et al.* (1990). In the *Visual thesaurus*, the basic meanings indicated graphically by small circles are correlated with definitions which appear in boxes when pointed at by the mouse; they can also be called up and compared with related ones in a marginal column on the right side of the screen.

('upholstered seat for more than one person') leads on to the synonyms *lounge* and *sofa*, and from the latter further to 'upholstered seat for more than one that can be changed into a bed' with two synonyms (*sofa bed* and *convertible*) and to 'small sofa for two' with two more (*love seat* and *tête-à-tête*).

This is one of several modes of presentation that are becoming available in the early 21st century, although it is difficult to keep track of the emerging formats and the terminological classification, qualitative evaluation, and pedagogical integration of these digital reference media. Thus, Yukio Tono (2004) distinguished five types of electronic interface (CD-ROM, Hyperlink, Pop-up mode, Parallel format, and Pocket e-dictionary), but little is known about the advantages and limitations of specific digital and Web-based products. The new generation of CD dictionaries, for example, *Genie*, which is linked to the *Oxford advanced learner's dictionary*, can be used for word searches, text searches, and sound searches in both decoding and encoding contexts. Thus, for the word *couch*, a range of synonyms and other related words will appear, from *armchair* and *chaise longue* to *lounger* and *sofa*, together with definitions and examples. Collocational information is also included, as well as links to illustrations and study pages.

For users with appropriate IT skills, these reference experiences are promising indeed. However, instruction and persistence are often required to exploit them fully on a practical level; ideally the 'new' material needs to be tested against both user practices for their effectiveness and corpus evidence for their reliability (Sierra Martinez, 2000). To verify exactly what denotational and connotational differences there are between words like *couch* and *sofa*, for example, would in turn require more interdisciplinary contacts with such fields as semantics, sociolinguistics, and computational linguistics.

Many other fields of relevance could be mentioned. Some that have been covered here include history and linguistics; others not covered include neurolinguistics (how is vocabulary stored in the brain?), education (how are users, specifically language learners, taught to find and interpret information in thesauruses?), and the various disciplines that have been the subject of encyclopedic or terminological reference works.

Thetic–Categorical Distinction

H Haberland, University of Roskilde, Roskilde, Denmark

In the late 19th and early 20th century, there were two major attempts at overcoming the Aristotelian articulation of the clause (or 'judgment') in subject and predicate: one by Gottlob Frege (*see* **Frege, Gottlob (1848–1925)**), who did away with the distinction altogether, and one by Franz von Brentano and Anton Marty, who restricted the traditional subject–predicate articulation to what they called 'categorical judgments,' as opposed to 'thetic judgments,' which do not involve an act of predication about some 'psychological subject' but attribute something to a situation as a whole.

This suggestion was later taken up by the Czech linguist Vilém Mathesius (1929) (*see* **Mathesius, Vilém (1882–1945)**), who saw the sentence as a communicative utterance by which the speaker assumes some active attitude to some fact or group of facts (1983: 124). In declarative sentences, this active attitude is assertion. An assertion can either be the simple presentation of an event or action (like in Czech *byla tma* 'it was dark'; thetic) or a predicative statement about a theme (*and the king had a beautiful daughter*; categorical).

It was not until 1972 that the U.S.-Japanese linguist Sige-Yuki Kuroda rediscovered the Brentano-Marty proposal. He argued that the much discussed difference between the Japanese 'subject' particle *ga* and the 'topic' particle *wa* actually reflected a distinction between two judgment types, viz., the categorical and the thetic. At the time of its publication, however, Kuroda's paper did not have too much impact, as another U.S.-Japanese scholar, the Harvard linguist Susumo Kuno (1972), had just proposed a different explanation of the same phenomenon in terms of information structure: the *ga*-clauses in question were 'neutral descriptions,' which contained all new information, while *wa*-clauses were about some (given or contrasted) topic. This proposal tailed in with a long-standing discussion about 'accented subjects' in English (see Bolinger, 1954; Fuchs, 1980) and similar phenomena.

A number of scholars of Romance languages (such as Vattuone (1975) on Genoese Italian and Ulrich (1985) on Romanian) maintained that the word order verb–subject (VS, in contrast to subject–verb, SV) in these languages codes thetic judgments. (Similar observations have been made for Hungarian, Russian, Bulgarian, and Modern Greek.) This claim was taken up by Hans-Jürgen Sasse in 1987. His point is that the thetic/categorical distinction (which he relates to the sentential communication perspective) is independent of the information-structure phenomena described by Kuno (which Sasse associates with discourse–pragmatic presuppositions). (*see* **Pragmatics: Overview; Discourse, Foucauldian Approach**.)

If thetic judgments were simply 'neutral description' sentences, they would be the appropriate answer to questions (such as '*What happened?*') that do not introduce any discourse-pragmatically presupposed material (*see* **Presupposition; Pragmatic Presupposition**). But while such questions are a valid diagnostic for neutral descriptions (and 'all-new' sentences), they fail as a diagnostic for thetic judgments. In answering, the speaker still has a choice between, for example, VS and SV forms in Italian: he or she can either focus on the situation as a whole and make a statement

Thetic–Categorical Distinction

H Haberland, University of Roskilde, Roskilde, Denmark

In the late 19th and early 20th century, there were two major attempts at overcoming the Aristotelian articulation of the clause (or 'judgment') in subject and predicate: one by Gottlob Frege (*see* **Frege, Gottlob (1848–1925)**), who did away with the distinction altogether, and one by Franz von Brentano and Anton Marty, who restricted the traditional subject–predicate articulation to what they called 'categorical judgments,' as opposed to 'thetic judgments,' which do not involve an act of predication about some 'psychological subject' but attribute something to a situation as a whole.

This suggestion was later taken up by the Czech linguist Vilém Mathesius (1929) (*see* **Mathesius, Vilém (1882–1945)**), who saw the sentence as a communicative utterance by which the speaker assumes some active attitude to some fact or group of facts (1983: 124). In declarative sentences, this active attitude is assertion. An assertion can either be the simple presentation of an event or action (like in Czech *byla tma* 'it was dark'; thetic) or a predicative statement about a theme (*and the king had a beautiful daughter*; categorical).

It was not until 1972 that the U.S.-Japanese linguist Sige-Yuki Kuroda rediscovered the Brentano-Marty proposal. He argued that the much discussed difference between the Japanese 'subject' particle *ga* and the 'topic' particle *wa* actually reflected a distinction between two judgment types, viz., the categorical and the thetic. At the time of its publication, however, Kuroda's paper did not have too much impact, as another U.S.-Japanese scholar, the Harvard linguist Susumo Kuno (1972), had just proposed a different explanation of the same phenomenon in terms of information structure: the *ga*-clauses in question were 'neutral descriptions,' which contained all new information, while *wa*-clauses were about some (given or contrasted) topic. This proposal tailed in with a long-standing discussion about 'accented subjects' in English (see Bolinger, 1954; Fuchs, 1980) and similar phenomena.

A number of scholars of Romance languages (such as Vattuone (1975) on Genoese Italian and Ulrich (1985) on Romanian) maintained that the word order verb–subject (VS, in contrast to subject–verb, SV) in these languages codes thetic judgments. (Similar observations have been made for Hungarian, Russian, Bulgarian, and Modern Greek.) This claim was taken up by Hans-Jürgen Sasse in 1987. His point is that the thetic/categorical distinction (which he relates to the sentential communication perspective) is independent of the information-structure phenomena described by Kuno (which Sasse associates with discourse–pragmatic presuppositions). (*see* **Pragmatics: Overview; Discourse, Foucauldian Approach**.)

If thetic judgments were simply 'neutral description' sentences, they would be the appropriate answer to questions (such as '*What happened?*') that do not introduce any discourse-pragmatically presupposed material (*see* **Presupposition; Pragmatic Presupposition**). But while such questions are a valid diagnostic for neutral descriptions (and 'all-new' sentences), they fail as a diagnostic for thetic judgments. In answering, the speaker still has a choice between, for example, VS and SV forms in Italian: he or she can either focus on the situation as a whole and make a statement

about this, or choose a topic as a predication base and predicate something about this topic. This topic would then be new in the given situation; the resulting sentence is a categorical, all-new sentence.

Grammatical structure can be said to have two core articulations: a semantic articulation as predication and a topicality articulation as judgment. But there is also another, pragmatic articulation, that of given vs. new (Haberland and Nedergaard Thomsen, 1993: 177). Whether the thetic/categorical distinction is grammatically relevant depends on whether a language emphasizes topicality articulation (situational pragmatics) rather than information structure (discourse pragmatics). In other words, the question is whether the available syntactic means are more suited for expressing a thetic/categorical than an information structure-based distinction. So far, the following syntactic phenomena have been suggested as realizing the thetic/categorical distinction:

Noun incorporation:
Boni (Sasse, 1984)

Verb–Subject order:
Genoese Italian (Vattuone, 1975)
Romanian (Ulrich, 1985)
Modern Greek (Sasse, 1987)
Swahili (Sasse, 1987)

Split structures:
French (Ulrich, 1985; Sasse, 1987)

Dummy subjects:
Danish (*der*) (Heltoft, 1993)

Intonation features ('accented subjects'):
English (Sasse, 1987)
German (Sasse, 1984)
Morphological marking:
Japanese: *wa* versus *ga* (Kuroda, 1972; Shibatani, 1991)

Lambrecht (1987, 1994) has proposed a more fine-grained typology of focus that aims at capturing both the phenomena analyzed by the information-structure approach (as outlined by Kuno) and the thetic/categorical approach *à la* Kuroda, Sasse, and others (for a discussion, see Van Valin, 1990). In Lambrecht's approach, thetic judgments are cases of sentence focus.

A very critical discussion of the issue can be found in Wehr (2000).

Think-Aloud Protocols

S Tirkkonen-Condit, University of Joensuu, Savonlinna, Finland

What Is a Think-Aloud Protocol?

Think aloud (TA) is a method of eliciting data about the cognitive and linguistic processes that go on in the translator's mind while translating. Think aloud refers to spontaneous concurrent task-related verbalization during task performance that ideally takes place virtually without prompting. The term 'think aloud' is sometimes also used to refer to retrospective sessions in which the subject is asked to comment on the task after its performance, but in this article the term is confined to concurrent verbalization. Also, 'think aloud' is here confined to solitary thinking aloud and, thus, does not include dialogue protocols, which are transcripts of discussions in joint translation sessions.

In a typical experimental design, a translator is asked to 'think aloud' while carrying out the translation brief, i.e., to verbalize his/her thoughts to the extent that this is possible without hampering task performance. The tape-recorded or videotaped think-aloud session is transcribed into think-aloud protocols (TAPs), which are then subjected to the kind of analysis that is needed to answer the research question at hand. The degree of accuracy and the notations used in the transcription also depend on the aim of the research, but it is advisable to transcribe the material carefully, following, e.g., the standard procedures used in conversation analysis. It is customary to include in the transcription such nonverbal items as the length of pauses, intonation patterns, and paralinguistic phenomena (laughter, sighing, exclamations, cursing, etc.). Careful transcription also makes the protocol accessible for other researchers and improves its usability for a greater variety of research purposes.

The TAPs, together with the translation product itself, constitute the raw data that are generated in a think-aloud session, and they can at best give a glimpse into the translator's mind. Complemented with other data, such as a tape-recorded retrospective interview with the translator or a log of the translator's keyboard activity, TAPs can turn out a valuable source of information that cannot be accessed by any other methodology. Think-aloud data in translation studies have been criticized, e.g., for being fragmentary; for representing the products of cognitive processes instead of the processes themselves, and for the potentially detrimental effects of TA on the processes. For concise reviews of this discussion, see Jääskeläinen (1998: 266–267) and Bernardini (2001). By carefully planning the experimental session, however, some of the imminent problems can be avoided.

How to Set Up an Experimental Session with Think Aloud

The aims of think-aloud experiments vary, but normally the researcher wishes to capture the translation process as intact and authentic as possible. Therefore, the session should be administered in such a way that the translator does not find the experimental situation stressful. A stressful and artificial situation will distort the translator's task performance, and her think-aloud data will not reflect her normal thinking. One way to foster ecological validity is to administer the experimental session in the translator's own office, where she has access to the tools and contacts that she normally uses in her work. It is also recommended that a warming up task should be administered in order to give the subject a chance to try out thinking aloud in advance of the experimental task. Another recommendation is that the task description should be given clearly and unambiguously and that it should also be available in a written format. This is necessary, if the aim is to enable other researchers to replicate the experiment.

An important caveat concerning think aloud is that the subjects in a think-aloud experiment should be encouraged merely to verbalize freely, i.e., to think aloud instead of analyzing, commenting on, or telling the experimenter what they are doing. If the subject falls silent for a long period, the experimenter can give a simple prompt to encourage the subject to carry on thinking aloud, but the subject should not be asked to explain, justify, or report on his or her performance.

For example, if the aim of the research is to find out on what grounds professional translators add explicating items, e.g., adversative connectives (cf. Englund Dimitrova, 2003), in their translations, the researcher probably chooses a source text and a task description in which some items are likely to trigger off such additions. If the expected behavior does not take place, i.e., if the subject does not react to the source text as expected, the experimenter refrains from prompting the subject to comment on the item or phenomenon, even though it is in focus in the research design. Thinking aloud should be spontaneous; otherwise, it is not thinking aloud at all, and this is probably the biggest problem inherent in this method of data elicitation (see 'Constraints and Limitations' section).

In order to find out how the subject reacted to the experimental situation and perhaps to get some

further information that may explain aspects of task performance, it is recommendable to arrange a retrospective interview with the translator right after the experimental session itself. This is a session in which the subject is asked to comment on the session as a whole, and which gives the researcher the opportunity to find out, for example, if the subject felt that he was performing naturally or whether the think-aloud condition was disturbing in some respect. The subject could also be asked to evaluate the quality of his performance in the test and to compare it to his normal level of performance.

Why Investigate Think-aloud Data?

TAPs have been analyzed to investigate, e.g., translators' problem-solving, decision-making, information search, and motivation. Subjects representing varying levels and domains of expertise have been used in order to identify those process features that go together with expert-level performance (e.g., Tirkkonen-Condit, 1996; Jääskeläinen, 1999; Livbjerg and Mees, 2002; Sirén and Hakkarainen, 2002). The effect of the familiarity of the translation assignment on the process was investigated by Laukkanen (1997), the effect of time pressure by Jensen (2000), and the effect of access to dictionaries by Livbjerg and Mees (1999).

The first major research projects based on TAP data (Gerloff, 1986, 1988; Krings, 1986, 1988; Lörscher, 1986) came out virtually simultaneously in the late 1980s. These pioneering studies aimed at identifying the overall features of the translation process; in other words they set out to investigate 'what happened in the translator's head' and to devise methods of analysis to describe what they found.

Transcripts of think-aloud sessions seem very confusing, if the research questions are of such a global nature as they tended to be at first. Below are two excerpts of a think-aloud protocol in which a Finnish translator is dealing with the English expression *vulnerably housed* in an experimental session administered by the present writer herself (for a report of the experiment, see Tirkkonen-Condit, 2002). The original TAP excerpts are accompanied by their translations into English. The figures in brackets indicate the length of pauses in seconds; underlined pauses in brackets stand for those pauses during which typing takes place; (.) stands for a pause shorter than one second; (hh) indicates a sigh with an out-breath; and (( )) for inaudible verbalization. A lengthened end vowel is marked with a double colon.

vulnerably (12) (reading a dictionary entry) vulnerably housed (14) haavoittuva herkkä uhanalainen suojaton (2) hmm (2) entäs tuo housed sitten (( )) (18) house kyllä löytyy (3) onkos tuo nyt oikein (3) on (6) en tiennykään että housella on monia monta merkitystä (6) the club is housed (.) there (.) kerho sijaitsee siellä (.) (( )) (2) hmm (1) vulnerably housed (5) voi räkä tämä on joku sanonta (4) (( )) (moving the microphone) (18) hh (2) siis jotenkinhan tämä liittyy köyhyyteen asunnottomuuteen (25) to house on majoittaa (2) voiskohan tämä olla ettei oo pysyvää asuntoo tai asuinpaikkaa (4) tai sitten mie yhistän nämä kaikki kolme (2) kodittomat ja entiset kodittomat ja (6) taidan tarjota ei pysyvää asuinpaikkaa (3) hh

se on tuo (.) vulnerably housed taas kummittelemassa (1) (( )) (13) irtolainen on varmaan vähän (.) arvoväritteinen (laugh) (6) hh tarjotaan nyt sitten ilman vakituista (.) asuinpaikkaa:: (17) (( )) (2) vaatii jottain lissää tähän

[vulnerably (12) (reading a dictionary entry) vulnerably housed (14) woundable sensitive threatened without shelter (2) hmm (2) what about housed then (( )) (reading a dictionary entry) house is there alright (3) but is this one correct (3) yes it is (6) I did not know that house has several meanings (6) the club is housed (.) there (.) the club is located there (.) (( )) (2) hmm (1) vulnerably housed (5) heck this is some idiom (4) (( )) (moving the microphone) (18) hh (2) so this has something to do with poverty having no place to live (25) to house means to accommodate (2) could this mean that someone does not have permanent dwelling or place were to live (4) or then I will put all the three things together (2) homeless and ex-homeless and (6) I might offer with no permanent place to live (3) hh]

[there's this (.) vulnerably housed haunting me again (1) (( )) (13) a tramp is probably a bit (.) loaded (laugh) (6) hh okay lets just offer without permanent place to live (17) (( )) (2) it needs some padding here]

The above excerpts show that the translator ultimately figured out, with the help of a dictionary, that *vulnerably housed* probably referred to people with no permanent place to live.

The early researchers were wondering, for example, what the unit of analysis should be and on what basis stretches or passages in the ongoing verbalization should be segmented and categorized. Krings (1986) decided to use the translation problem as the unit of analysis. The entity of translation problem was operationalized by establishing a number of unambiguous problem indicators, which included pauses of three seconds or longer, gaps in the translated text, production of multiple translation variants, and expressions of ignorance. Categorization and counting of the problems generated data that enabled the researcher to make intersubject comparisons as well as process versus product comparisons. A similar method was subsequently developed for the categorization and analysis of translational decisions by Tirkkonen-Condit (1991).

In the 1990s, the popularity of think aloud in process-oriented research was reflected in the

contemporary review articles and collective volumes, which focused almost entirely on studies that used TA as the main method of data elicitation. The review article by Kussmaul and Tirkkonen-Condit (1995) on process research carried out in Europe, for example, discussed mainly TA projects, although a couple of studies based on dialogue protocols were also included.

Another feature shared by early process studies is a concern for transferring research findings to translation pedagogy. This is not surprising, as the researchers were themselves teachers of translation in departments of foreign languages or in schools of translation studies, where they had access to voluntary subjects for experiments. Whereas Pamela Gerloff, Hans-Peter Krings, and Wolfgang Lörscher in their pioneering work were primarily focused on identifying the nature of process phenomena, most of the other researchers in the 1980s and early 1990s were already on the lookout for applications. Pedagogical relevance is clearly highlighted in the work of Donald Kiraly, who challenged the didactic routines of a teacher-centered translation class and argued for a constructivist approach to learning and teaching (Kiraly, 1995). Paul Kussmaul with his colleague Hans Hönig also used students' performance as a database, and focused on identifying such strategies for solving translation problems that could be taught to novices in translation (e.g., Hönig, 1988; Kussmaul, 1995). Frank G. Königs deserves to be mentioned among those whose empirical findings from translation students' performance contributed to the theory of the translation process as early as the 1980s (Königs, 1987, 1991). In his 1987 article, he divided the translation process in two blocks, with the Adhoc block standing for automatic processing and the Rest block for conscious processing. The hypothesis of static automated blocks was challenged by Jääskeläinen and Tirkkonen-Condit (1991) by virtue of empirical evidence that showed that automation could also happen during the process, and that seemingly automated solutions could be subjected to conscious treatment.

The special issue of *Meta* on Translation Processes edited by Königs in 1996 reflects the state of the art at the time but also the trends for the years to come. Some papers still aim at capturing the essence of the entire process, while others focus on the strategic dimension (Mondahl and Anker Jensen) or particular aspects of the process (Tirkkonen-Condit and Laukkanen). This collection in the main represents what Jääskeläinen (1999) called first-generation research, in that the contributions, the empirical papers in particular, start from scratch as it were, i.e., the findings from their own small-scale pilot studies, and then go on to sketch hypotheses for future testing.

For obvious reasons, first-generation research dominates the collective volume edited by Candace Séguinot in 1989. Séguinot herself was one of the first scholars who set out to investigate what happened in the minds of real professionals in the translation industry as they carried out their routine tasks. One important observation was that highly experienced professional translators did not necessarily verbalize very much when performing their routine tasks. Processes that call for conscious decision making and problem solving from the novice become automated for the expert and will not surface in the expert's TA unless explicitly prompted. The translator who functioned as subject in Séguinot's (1989) study worked in the Department of the Secretary of State, and for the purposes of the experiment, chose a text from the pool of texts that were due for translation in the English Section. Even though verbalizing was scarce, there were signals in the typing performance that revealed potential decision points and some other reasons for deviating from 'smooth' target language rendering. The most obvious signals of deviations from smooth rendering were pauses and revisions. A comparison of source and target texts, however, yielded perhaps the most interesting findings of the entire study, namely the fact that the professional translator changed the text in several respects while translating it. The target text manifested increased objectivity, improved logic, greater explicitness, greater precision, improved coherence, sustained register, and tendency to brevity (Séguinot, 1989: 25–30). The necessity to improve the text is widely acknowledged by those who translate nonliterary or functional texts (see e.g., Nida, 2002).

The scarcity of verbalization in the professionals' think-aloud protocols may have led Séguinot to question the usefulness of TA as a method of data elicitation altogether (see Séguinot, 1996) and to look for other methods. Thus for another study somewhat later, Séguinot tape-recorded two experienced translators' conversations while these were working as a team to produce translations for publication (Séguinot, 2000). It turned out that the professional translators' dialogues revealed 'managerial' aspects of task performance that would hardly have surfaced in solitary think aloud, let alone leave a trace in the product. A discussion on 'Think Aloud Versus Dialogue Protocols' appears later in this article.

An Overview of the Major Results

One of the main findings in TAP research, and in process research at large, is that it is dangerous to make sweeping generalizations about translation processes. There is wide individual variation in the processes of

novices as well as those of skilled professionals. It has turned out, for example, that professional status does not necessarily guarantee high-quality performance, and conversely, that novices' performance may manifest features of expertise. This finding has important consequences for research that aims at identifying elements of expertise in translation processes. It means that studies of processes must be accompanied by an evaluation of product quality as well.

Another major finding relates to the discussion on automated processing in translation. It had turned out that professional translators, while carrying out their routine assignments in experimental sessions, often fell silent for long stretches of time. This phenomenon in turn was accounted for by the psychological fact that cognitive processes tend to become automatic through repeated practice (e.g., Ericsson and Simon, 1984). This led some researchers to conclude that there was no access to professional processing via think aloud. As other researchers continued getting ample evidence to the contrary, the outcome of the discussion was that the propensity to think aloud depended on the type of assignment. A translation brief that called for the translator to repeat a well established routine did not necessarily trigger off conscious decision-making, let alone problem-solving, and thus virtually no spontaneous verbalization. In contrast, a new kind of translation assignment, a nonroutine task, was found to generate spontaneous thinking aloud.

One observation, however, is probably shared by everybody who has been involved in TA experiments, namely the observation that there are some people for whom the think-aloud condition is so unnatural that it is bound to affect their performance and thus the ecological validity of the results. On the other hand, there are those who recognize thinking aloud, or subvocal verbalization, as their normal condition when carrying out a cognitive task, be it translation, a mathematical puzzle, or figuring out a location on the map. Most people probably fall in between these two extremes. This relates to the constraints and limitations of TA to be discussed in the 'Constraints and Limitations' section of this article.

Although there is great individual variation even among expert-level translators, there are still a number of shared features of expertise that emerge in several studies. An overview of these features is given in Tirkkonen-Condit (1996), and it is summarized in what follows. Here the term 'expertise' is preferred to professionalism, as the focus is on processes that are observed to result in successful performance. Expertise captures the idea that it is not professional status we are interested in but expert-level performance and the processes that account for it.

When the translation process is described in terms of the knowledge base utilized by the translator, expertise is characterized by a highlighted proportion of knowledge inferred from the source text. Whereas novices and nonexperts tend to focus on lexical items and other microlinguistic aspects and to resort to text-external translation aids for information, experts tend to focus on the text itself and to maximize the amount of information to be gleaned from its semantic, pragmatic, and intertextual dimensions. Nonexpert comprehension procedures tend to be locally oriented, while expert comprehension procedures tend to be globally oriented.

A similar local versus global distinction is to be found in the text generation procedures of nonexperts and experts. A feature typical of experts' text generation is that some decisions about the entire target text are made at a relatively early stage of the process. Among such global decisions can be, for example, decisions about the overall style of the emerging target text. If a translator decides, for example, to use an overbearing tone, then she will discard such translation variants that give an impression of compliance or pleasantness. One way of analyzing think-aloud protocols from the point of view of stylistic decisions is to look at the adjectives that the translators use when evaluating potential translation variants or the text that has already been produced. The adjectives reflect the general impressions the translators are aiming at, as well as the impressions they wish to avoid. One translator, for example, expressed desirable qualities with such adjectives as *natural, balanced, lucid, pleasant, elegant, simple,* and undesirable qualities with expressions such as *simplistic, mild, pedantic.*

Experts have also been found to behave according to their global decisions and according to the principles they have adopted, while no similar compatibility between global aims and local decisions has been found in nonexperts' protocols. On the contrary, there is often a conflict between voiced principles and action. Subjects representing nonexpert performance may emphasize the importance of reference material or expert help, but in local decision-making situations end up just using a dictionary in spite of easy access to the Internet, the telephone, or the library. Such incompatibility between principles and local decisions is to be seen in the following TAP excerpt from Laukkanen's (1997) study:

> kuinkas pitkä tää nyt olikaan (1) ei kovin pitkä (1) nyt tää pitäis ensin lukea mutta (.) kaikkien taiteen sääntöjen mukaan (.) mut mä en aio lukea tätä (laughs) (5.0) ku ei näit yleensä jaksa eikä ehdi nii (.) tai sitä lukee sitä mukaa ku tekee et kyl siinä sitte huomaa jos tulee jotain outoo

> [let me see how long was this now (1) not very long (1) now then I should read this through first but (.) according to the rules of the game (.) but I'm not going to read it (laughs) (5) because you normally don't have the energy or the time so (.) or you just read it while doing it so you will see if something strange comes up]

Another feature of expertise is that decision-making effort is concentrated on those problem areas of the task that seem to have the greatest bearing on the outcome. Such crucial areas are, for example, titles and headings as well as pivotal terms, names, or acronyms that get frequently repeated in the text. The distribution of decision-making effort can be investigated by different methodologies developed within the TAP research tradition. One method is to identify all those sections in the protocols in which more than one potential translation variant is voiced for a particular section of the source text (see Krings, 1988). Accumulation of competing translation variants, or multiple variant production, implies a need for a conscious decision, i.e., a choice of just one variant and the rejection of others. In the performance of experts, multiple variant production has been observed to accumulate on those areas that have greatest weight in the entire assignment. Experts invest decision-making effort strategically instead of wasting it on irrelevant details.

Focus on target text generation and monitoring its quality show in the think-aloud protocols of experts also in the distribution of evaluative expressions. It has been shown (Tirkkonen-Condit and Laukkanen, 1996) that the proportion of target text evaluations (of all evaluative expressions identified in the TAPs) grows with the level of expertise. Research with other methodologies support the observation that expertise calls for monitoring skills (e.g., Sirén and Hakkarainen, 2002; Hansen, 2003).

Constraints and Limitations

With the caveat in mind that a TAP can, at best, only give a glimpse into the translator's mind, perhaps the most serious limitation of this method of data elicitation is that it is not applicable to all potential subjects. Some people simply cannot think aloud naturally. If they do not fall silent altogether, they may start giving a retrospective report of what they just did, or a report on what they are going to do next. Instead of thinking aloud by themselves, they talk to an addressee, even if there is no one present in the room. Inability to think aloud is not the only problem relating to suitability as a subject. The think-aloud condition may also be experienced as intrusive or embarrassing, which also endangers the validity of the data. A warming-up task should reveal if a subject feels at home with think aloud. If this is not the case, there is a good reason to give up the experiment or at least to treat the TA data with caution.

The problem of automated processes in the context of translation briefs of a routine type was mentioned earlier in this article. Thus, if the aim is to identify process features that may account for professional and expert-level performance, the experimental task should have elements that require detachment from everyday routines. The translation brief, for instance, that I used in a think-aloud experiment administered in the Helsinki-based translation unit of the European Commission elicited a good amount of thinking aloud from all the eight professional translators who took part in the experiment. Their routine tasks constituted mainly legal EU texts to be translated from English or French into Finnish, whereas the experimental task represented a less specialized field. Its description is given below in the format in which it was presented to the subjects (for details, see Tirkkonen-Condit, 2002):

> The following text appears on the cover page of a weekly publication sold on the street in Britain, called *The Big Issue* (as the text itself explains). In Finland some organizations of the unemployed have had a similar initiative in mind, and one of them has commissioned the English text to be translated into Finnish. The translation is needed as a basis for launching such an initiative in Finland.

In research that aims at optimal psychological and ecological validity, the think-aloud experiment should be administered in such a way that the translator's normal working habits are interfered with as little as possible, even though the translation brief itself deviates from everyday routines. Spontaneity of thinking aloud is the ideal, and prompting should be as unobtrusive as possible. Solicitation of explanations, justifications, descriptions, etc. will affect the spontaneity and authenticity of think-aloud data, which then does not really represent what goes on in the translator's mind, but rather what goes on in the experimenter's mind. A think-aloud session may of course be interrupted by 'normal' addressee-oriented talk, when, for instance, the experimenter and the subject are discussing the location or the functioning of the microphone, but this should not be confused with thinking aloud.

The effect of TA on processing has concerned the researchers themselves as well as their critics. One of the most influential of the latter is Gideon Toury, whom I quote in what follows (see Toury, 1995: 235–237):

> "My concern is rather with the *possible interference of two modes of translation*. Thus what the experiment claims to involve is basically the gradual production of

> a *written* translation of a *written* text. However, the need to verbalize aloud forces the subjects to produce not just *mental,* but *spoken* translation before the required written one; and there is a real possibility that spoken and written translation do not involve the exact same strategies." (Italics as in the original.)

Here Toury seems to assume that subjects in a think-aloud experiment are forced to produce a spoken translation before they type or write down their translation or part of it. This is a gross misunderstanding of how a normal think-aloud experiment is administered. If subjects in fact verbalize stretches of the enfolding target text in advance of typing it, they do it without an instruction to do so. It would be against the rules of think aloud as it were, if the administrator of the experiment asked the translator to translate orally – if the aim is to study processes that go on in the translator's mind while performing a (normal) written translation task. It may be the case that the experimenters that Toury has observed have forced their subjects to verbalize in advance what they are going to type but this kind of request seems very strange and, indeed, is not justified, let alone required, by the method itself. If this were the general practice in think-aloud experiments, then how were we to explain the fact that professional translators tend to fall silent in routine tasks?

Even though some of the criticism addressed at think aloud is obviously misguided, the potential effect of think aloud on the translation process itself should not be dismissed lightly. One hypothesis (see e.g., Toury, 1995: 236–237) is that think aloud may affect the size of the translation unit by making it shorter than it would be in a non-TA condition. This in turn may result in a tendency to translate verbatim. The hypothesis according to which TA tends to shorten translation units has in fact got support from Arnt Lykke Jakobsen's study, in which subjects translated with and without think aloud. In both conditions, their keyboard activity was logged, whereby it was possible also to identify segments of text that were produced between pauses of a certain length (see Jakobsen, 2003). In addition to having a shortening effect on translated segments, TA was also noticed to increase the frequency of revisions and, consequently, also to lengthen the time needed to perform the task at hand.

In the light of the above discussion, it seems justified to expect that TA probably affects the translation process in some way, even if the experiment is conducted carefully and without pressuring the translators to verbalize what they would not spontaneously verbalize while translating in a TA condition. Another project altogether would be to find out whether TA has an effect on the quality of translation. To my knowledge, this has not been done in any of the experiments in which the aim has been to identify the potential effects of TA on the translator's performance. If it is the case that TA has a detrimental effect on translation quality, this should be taken seriously. However, there is no evidence so far that this is the case. On the contrary, many of the professionals that have participated in the experiments carried out by myself and my colleagues have turned out high quality translations in spite of – or perhaps by virtue of – the TA condition.

Think Aloud Versus Dialogue Protocols

One of the proponents of dialogue protocols is Juliane House, who argues for their superiority in eliciting richer data on translators' choices than solitary thinking aloud (see House, 1988, 2000). Paul Kussmaul has also given joint translation tasks to translation students, whose discussions have been recorded and transcribed into dialogue protocols. One of his aims (see Kussmaul, 1991) has been to find out how creativity manifests itself in translation. It seems that pair work can be conducive to creative impulses, as there is also room for joking and carnivalism while carrying out the task as a joint effort. It may also be the case that the experimental condition is more relaxed and less threatening in joint translation, as the responsibility for the outcome is shared. Thus the use of joint translation and dialogue protocols especially for pedagogic purposes seems well justified.

Another well-known argument for the use of dialogue protocols instead of TAPs for data collection is that it is easier for people to talk to others than to themselves. Consequently, there is more material to transcribe and more data to analyze. It should be remembered, however, that the nature of the dialogical data is different, and that dialogue protocols do not represent translation as it happens in most translator's work place. Translators may negotiate the translation brief and other aspects of the assignment with their employers and colleagues, but most of the target text generation normally takes place on a solitary basis. If the aim is to find out process phenomena in solitary translation, dialogue protocols will not serve the purpose. For some research purposes it may be a good idea to combine the two methods: if the researcher is interested in the processes of metaphor translation, for instance, he or she may set up an experiment in which one and the same translation brief is given to a number of solitary translators who perform the task in a TA condition, and to pairs of translators whose discussions are recorded and transcribed into dialogue protocols. Thus, particular instances of metaphoric expressions can be

observed to compare the processes that enfold in solitary versus dialogical conditions.

Think Aloud and Triangulation of Methods

It is important to bear in mind that TAPs do not constitute a research method. They are just one method of eliciting data that is assumed to bear on the processes that go on in the translator's mind while translating. In thinking aloud the verbalization, if any, is fragmentary by nature, as it ideally represents the subject's solitary thinking and is not really meant for the benefit of others. Thus, it is normal that sections of the recording are inaudible, incomprehensible or difficult to interpret. In addition to vocalized elements, however, TAPs contain information on pausing and other nonverbal information that may help in the interpretation of the vocalized sections.

Among the promising new methods of data elicitation that can be used in combination with TAPs, supplementary to TAPs, or independently of TAPs, is the logging of the translator's text generation by means of software such as Translog (see Jakobsen, 1999). The software registers all keyboard activity and has a replay facility that makes it possible to observe the typing process as it enfolds in real time, or speeded up at will. It is interesting to observe, for example, if text generation proceeds smoothly, if it has a certain rhythm, and if the rhythm varies. It has been noticed, for example, that individual translators manifest varying temporal rhythms in their text generation (Jakobsen, 2003).

The raw data from Translog is confined to two items: the final printout of the translation and an accurate register of the typing process in terms of keyboard activity. There is accurate information about the timing of each key stroke, pauses of any size, revisions, misprints, deletions, etc. Quantitative intersubject comparisons of merely this raw data can be revealing, if, for example, we are in search of process features that go together with expert level quality. We might want to ask, for example, how a high-quality translation tends to be generated; is it via abundant revision and abundant waste of keyboard activity, or is it generated smoothly, with little revision and little back and forth movement?

Translog does not provide any information about the translator's thinking, but it can be combined with a retrospective replay session, in which the translator has a chance to comment on her text generation while watching how it appears on the computer screen. As Translog also keeps an accurate log of interim solutions, the translator in the retrospective replay session may still remember why a particular interim solution was discarded and did not end up in the version that was accepted for the final printout.

Translog has at least two advantages over think aloud. From the translator's viewpoint it is less obtrusive, and from the researcher's viewpoint it is less labor-intensive. Thus it enables collection of large quantities of data, assuming that there are enough translators who volunteer as subjects. Registering the eye gaze patterns of translators is another method that could perhaps be increasingly used to glean information of the cognitive processes that account for translational phenomena. Correlating quantitative data from various sources would enable us to test the hypotheses that have been suggested as a result of small-scale research with TA and other labor-intensive data collection methods (e.g., the hypotheses on expert versus nonexpert processes should be tested with large-scale quantitative research). Perhaps in the future it will be possible to set up large-scale projects on translation processes, in which quantitative analyses of data from various sources are carried out. Translogged data and eye-gaze data, for example, might be elicited from a great number of translators representing different levels of expertise, and the data might be correlated and subjected to statistical analyses. This is necessary, if we are to find out if there are indeed shared patterns that single out those translation processes that result in high-quality translation.

Conclusion

Bearing in mind the caveats, constraints, and limitations that accompany the use of TAPs, it can be concluded that, especially in combination with other methods of data collection, the think-aloud method should belong to the tool kit of a researcher who is interested in the workings of a translator's mind. As TAPs have also turned out pedagogically useful, they should belong to the tool kit of a teacher of translation as well.

Third Language Acquisition

J Cenoz Iragui, University of the Basque Country, Vitoria-Gasteiz, Spain

Introduction. The Spread of Third Language Acquisition: Sociolinguistic Perspectives

Third language acquisition is a very common phenomenon all over the world and occurs in a large number of diverse sociolinguistic situations. The number of languages spoken in the world nowadays (approximately 6,000) clearly outnumbers the number of countries (approximately 200) in which they are spoken, implying that going beyond second language acquisition is not unusual, and learning a third or a fourth language is natural for many people all over the world. Third language acquisition occurs commonly in bilingual and multilingual contexts, when, due to historical or political reasons, two or more languages overlap in a region, but also occurs commonly among individuals who need to communicate for professional or other reasons.

Third language acquisition is promoted in Europe within established linguistic minority groups (for example, Catalan, Basque, Frisian, or Welsh), whose members, as a matter of ethnic pride and cultural preservation, support learning and using their traditional languages in addition to the national language and languages of wider communication. It is also very common for immigrants to learn a third language. In some cases, immigrants are already bilingual or multilingual before they learn the language of the host country, and in non-English-speaking countries, they may also further their communication skills by learning English at school in the host country. In the United States, Canada, Australia, and New Zealand, immigration is a very common phenomenon. Members of minority communities in these countries speak their own heritage language (for example, Mohawk in Canada or Maori in New Zealand) or the immigrant language (for example, Spanish, Italian, or Chinese) and may learn English in schools (and in the case of children, additional languages) or as part of their assimilation education.

Bilingualism and multilingualism are extremely common in Asia and Africa. In some countries in these regions, many people use a variety of family and tribal languages plus a lingua franca and/or a national language, thus third language acquisition is a very common part of the culture. The teaching of additional languages at school also contributes to multilingualism. For example, speakers of Berber in Morocco learn Arabic, French, and some English at school; in South America, school is often the place where many children acquire a second and a third language. Native speakers of Quechua, Aymara, or Guarani, for example, usually learn Spanish as a second language and English as a third language.

Introduction. The Spread of Third Language Acquisition: Sociolinguistic Perspectives

Third language acquisition is a very common phenomenon all over the world and occurs in a large number of diverse sociolinguistic situations. The number of languages spoken in the world nowadays (approximately 6,000) clearly outnumbers the number of countries (approximately 200) in which they are spoken, implying that going beyond second language acquisition is not unusual, and learning a third or a fourth language is natural for many people all over the world. Third language acquisition occurs commonly in bilingual and multilingual contexts, when, due to historical or political reasons, two or more languages overlap in a region, but also occurs commonly among individuals who need to communicate for professional or other reasons.

Third language acquisition is promoted in Europe within established linguistic minority groups (for example, Catalan, Basque, Frisian, or Welsh), whose members, as a matter of ethnic pride and cultural preservation, support learning and using their traditional languages in addition to the national language and languages of wider communication. It is also very common for immigrants to learn a third language. In some cases, immigrants are already bilingual or multilingual before they learn the language of the host country, and in non-English-speaking countries, they may also further their communication skills by learning English at school in the host country. In the United States, Canada, Australia, and New Zealand, immigration is a very common phenomenon. Members of minority communities in these countries speak their own heritage language (for example, Mohawk in Canada or Maori in New Zealand) or the immigrant language (for example, Spanish, Italian, or Chinese) and may learn English in schools (and in the case of children, additional languages) or as part of their assimilation education.

Bilingualism and multilingualism are extremely common in Asia and Africa. In some countries in these regions, many people use a variety of family and tribal languages plus a lingua franca and/or a national language, thus third language acquisition is a very common part of the culture. The teaching of additional languages at school also contributes to multilingualism. For example, speakers of Berber in Morocco learn Arabic, French, and some English at school; in South America, school is often the place where many children acquire a second and a third language. Native speakers of Quechua, Aymara, or Guarani, for example, usually learn Spanish as a second language and English as a third language.

The role of English as the most important language of wider communication in the world also contributes to its dominance as a third language. The spread of English has been visualized by Kachru (1992) in terms of three circles. The innermost circle includes the countries that are traditionally considered the bases of English, where English is the first language for the majority of the populations (the United Kingdom, the United States, Ireland, Canada, Australia, and New Zealand). (As already noted, however, English is not the only language spoken in these countries and it is learned as a second or third language by members of minority communities.) The next circle outward includes those countries where English is not the first language for the majority of the population, but it is a second or third language that is used at the institutional level, as the result of colonization (India, Nigeria, Philippines, etc.). The expanding outermost circle includes those countries where English has no official status and is taught as a foreign language (Continental Europe, Japan, China, South America, etc.). As can be seen, speakers of English are in contact with speakers of other languages in all three circles, and therefore the third language acquisition of English is not unusual in most places in the world.

Despite third language acquisition being a common phenomenon, research in this field has received very little attention until recently. In the past decade, there has been a growing body of research into third language (L3) acquisition and multilingualism, as is reflected in an increasing number of publications in this area (for instance, Cenoz and Jessner, 2000; Cenoz *et al.*, 2001), in the publication of *The International Journal of Multilingualism*, and in the number of international conferences devoted to research on third language acquisition (held in Innsbruck, 1999; Leeuwarden, 2001; Tralee, 2003; and Fribourgh-Biel, 2005). The research has responded to the need to identify the specific characteristics that distinguish L3 acquisition and multilingualism from second language (L2) acquisition and bilingualism, and has addressed psycholinguistic, sociolinguistic, and educational issues. Research in this area tried to answer questions concerning the influence of bilingualism on L3 acquisition, whether L3 learners mix languages more than L2 learners do, how the first and the second languages affect the acquisition of additional languages, and which specific strategies are used by learners in L3 acquisition.

Differences between Second and Third Language Acquisition

Processes involved in the acquisition of a second or a third language have a lot in common, both theoretically and in terms of research methodologies. In both cases, researchers make theoretical proposals about the way learners process and use languages that are not their first language, and analyze learners' production of the target languages. However, there are important differences in the learning processes. These differences can be basically defined as 'process oriented' and 'product oriented.' Third language acquisition is a more complex phenomenon, compared to second language acquisition, and entails some specific characteristics. Learners, having already faced the task of acquiring a non-native (second) language, have gone through the process of developing learning strategies and metalinguistic awareness. The 'product' resulting from the process of acquiring a second language – that is, communicative competence in the second language – can influence how learners acquire a third language. This effect has been described in studies of the cross-linguistic influence in third language acquisition. The process of acquiring a third language can be considered more complex in terms of research because it involves all of the factors related to second language acquisition, plus additional factors related to the size of the learner's linguistic repertoire and his/her experience as language learner:

> Multilingual acquisition and multilingualism are complex phenomena. They implicate all the factors and processes associated with second language acquisition and bilingualism as well as unique and potentially more complex factors and effects associated with the interactions that are possible among the multiple languages being learned and the processes of learning them. [Cenoz and Genesee, 1998, 16]

The range of situations in which a third language may be acquired is also potentially quite broad. Languages may be acquired either simultaneously (early bilingualism or early trilingualism) or consecutively. A third language may also be acquired following the simultaneous acquisition of two languages, or simultaneously with a second language. These situations could become even more complex if the process of acquiring different languages is interrupted and resumed.

Second language acquisition can take place formally (through instruction), naturally (outside school), or by a combination of instruction and natural acquisition. When several languages are involved, there is more potential for diversity. Ytsma (2001) proposed a typology of trilingual education that includes 46 types and is based on factors such as the linguistic distance between the languages involved, the use of the third language in the sociolinguistic context, or the age of introduction of the third language. For example, the three languages may be typologically related to

each other, as in the case of trilingual programs in Friesland, where English is learned as a third language after Frisian and Dutch, or two of the three languages involved may be typologically related to each other but unrelated to the other, as in the case of immersion programs in Finland involving Finnish, Swedish, and English. Other variables, such as the sociocultural status of the languages, also entail greater diversity when more than two languages are involved. For example, in Luxembourg, the second and third languages used in schools (French and German) are considered more prestigious than the first language. In Quebec, Canada, double-immersion programs (see Genesee, 1998) expose learners who speak English as their first language to French and Hebrew as languages of instruction.

The areas of research that have received the greatest attention when comparing second and third language acquisition are metalinguistic awareness and learning and communicative strategies (for a review, see Cenoz, 2003a). Research on the effects of bilingualism on metalinguistic awareness has associated bilingualism with a higher ability to reflect on language and to manipulate it. Bialystok (2001) observed that bilinguals tend to obtain better results in tasks related to word awareness and in tasks that demand high levels of control of attention. A number of studies have been reported that multilinguals use a wider variety of processing strategies. In a series of comparisons of monolinguals and multilinguals learning artificial linguistic systems (see, for example, Nayak *et al.*, 1990), it was found that multilingual persons demonstrated greater flexibility in switching strategies according to the demand characteristics of the task; for example, they preferred mnemonic strategies for a memory task and linguistic strategies for a rule-discovery task, they were more likely to modify strategies that were not effective in language learning, and they more effectively used implicit learning strategies. Their superiority in these domains was attributed to their experience as language learners.

According to some research studies, bilingual children are more sensitive to the communicative needs of their interlocutors and use more varied communication strategies. This enhanced ability may be related to the fact that bilinguals have to keep their languages separate and have to switch languages according to the needs of different situations.

Third Language Acquisition Research

Though the focus of research on third language acquisition is potentially broad in scope, so far it has been limited to a few specific aspects of language acquisition: the effect of bilingualism on third language acquisition, the acquisition of a third language at different ages, and the cross-linguistic influence from the first and the second languages into the third one.

Effect of Bilingualism on Third Language Acquisition

One of the main areas of interest in third language studies is analysis of the influence of bilingualism on learning another language; this has been achieved by comparing bilingual and monolingual learners during acquisition of a third language. These studies tend to confirm the advantages that bilinguals have over monolinguals in language learning. Studies concerning general aspects of proficiency indicate that bilingualism has a positive effect on L3 acquisition when it takes place in additive contexts and when bilinguals have acquired literacy skills in both of their first two languages. For example, research on the acquisition of French as a third language in Canadian immersion programs indicates that bilingual children score higher on French language tests than do their monolingual counterparts (see Bild and Swain, 1989). Similar results were obtained by Thomas (1988), who compared the scores on French tests of English–Spanish bilinguals to those of English-speaking monolinguals. Research conducted in Catalonia and the Basque Country also confirms these results (for a review, see Cenoz, 2003a).

However, not all research studies report positive effects of bilingualism on L3 acquisition. Some studies comparing the degree of proficiency achieved in the third language by bilingual immigrant students and majority-language students have reported no differences. For example, Sanders and Meijers (1995) and Van Gelderen *et al.* (2003) did not find any advantages associated with the acquisition of English as a third language when they compared monolingual Dutch speakers and bilingual immigrant students who had Turkish or Moroccan Arabic as their first language. These results may be related to the sociolinguistic context in which the research took place, and it is important to bear in mind that L3 acquisition is a complex phenomenon affected by a large number of individual and contextual factors, and bilingualism is one of these factors but not necessarily the most important factor in L3 acquisition.

Research on very specific areas of language proficiency tend to confirm the advantages of bilinguals over monolinguals, but this trend has not been confirmed in all cases (Cenoz, 2003a). Nevertheless, when it comes to very specific aspects of proficiency, the comparability of the results of these studies is severely limited by their diversity regarding the

specific areas of language proficiency tested and their different research methodologies.

Age and Third Language Acquisition

Third language acquisition can take place at different times in life. In the case of early trilingualism, children are exposed to three languages from a very early age. There are several case studies on early trilingualism (see Quay, 2001), but it is difficult to say how widespread early trilingualism is. Most research studies and reports have been written by European and North American parents who are, in most cases, linguists or language teachers and who have decided to follow a specific language policy and speak different languages at home. Early L3 acquisition also occurs naturally as the result of immigration by families to areas where two or more languages are spoken. The many different situations in which early L3 acquisition takes place depend on factors such as the languages used by each of the parents when addressing the child, or used between the parents, and the languages used in education. Other factors are the discourse strategies used by parents or their attitudes toward multilingualism.

There have been very few research studies on early trilingualism, and most have focused on language mixing, because this is the most noticeable characteristic of multilingual production. When considering the relative proportion of language mixing in the child's production of speech, in the case of early trilingualism, most parents and researchers report that children tend to mix their languages at the onset of speech production but that there is separation of the language systems afterward. There is not enough evidence in the case of early trilingualism to support either the 'mixed' or the 'separate' systems hypotheses. Language mixing at the onset of speech production is not necessarily evidence for mixed language systems, because children may produce words in other languages as a strategy when they have a lexical gap. Language mixing may also be related to language mixing by adults; as Nicoladis and Genesee (1997) observed, the parents' language mixing can have an effect on their children's language mixing.

The acquisition of a third language at school is probably a more common event than early trilingualism is. Second and third languages can be taught as school subjects or can be used as languages of instruction, as is the case in immersion programs. Research on the age factor in L2 and L3 acquisition indicates that instruction in foreign languages from an early age, in the school context, does not necessarily mean higher achievement in all cases. When instruction in the third language is limited to a few hours a week, older children make more progress than younger children do, but when instruction is more intensive and the second and third languages are used as languages of instruction, the results can be more positive for early starters (see Genesee, 1998; Cenoz, 2003b).

Cross-Linguistic Influence in Third Language Acquisition

Contextual interactions that occur when learners are exposed to more than one language and particularly the influence of the first and second languages on the third language are primary areas of research in third language acquisition studies. Such research highlights the differences between processes involved in L2 and L3 learning and has important implications for broader theories of language acquisition. Specific areas of investigation include the effects of different factors (such as typological distance, L2 status, proficiency, or time of acquisition) on cross-linguistic influence from L1 and L2 on L3. Speakers borrow more terms from the language that is typologically closer to the target language. For example, Cenoz (2003c) observed that learners used Spanish more often than Basque as the source language of borrowings into English both when Spanish was the first language and when it was the second language.

Another factor that can predict cross-linguistic influence is the so-called foreign language effect, or L2 status (Hammarberg, 2001). Several studies have reported that learners tend to use the L2 or languages other than the L1 as the source language of cross-linguistic influence (Clyne, 1997; Williams and Hammarberg, 1998), but typology seems to be stronger than L2 status when learners choose their source language for borrowing into the third language. Cross-linguistic influence in L2 acquisition has been related to the level of proficiency in the target language; less proficient learners have been reported to transfer more elements from their first language, compared to learners who present higher levels of proficiency (Ringbom, 1987). Even though it has also been suggested that transfer is more likely from the first language than from subsequently learned languages (Ringbom, 1987), such effects seem to be less potent than typological similarity between the languages. Another factor that can potentially affect cross-linguistic influence is 'recency' (see Hammarberg, 2001). It is hypothesized that learners are more likely to borrow from a language they actively use than from other languages they may know but do not use.

Other factors that can determine cross-linguistic influence are related to the specific context in which communication takes place, including the interlocutors, the settings, and the topics of the conversation.

Grosjean (1998) considered that these factors determine if the speaker is in a bilingual or a monolingual mode. The influence of the contextual factors that determine the speaker's mode has been confirmed in some L3 studies. For example, Dewaele (2001) found that the level of formality affects the total number of terms transferred from the L2 in L3 production, and the percentage of mixed utterances was higher in informal situations.

Multilingual Competence and the Multilingual Mind

Acquiring communicative competence involves the acquisition of linguistic, sociolinguistic, discourse, pragmatic, and strategic competence. When several languages are involved, as in third language acquisition, it seems quite unrealistic to expect learners to acquire a native-speaker level of competence with regard to all of the different components. In fact, the traditional idea of competence as related to second language acquisition has been challenged. Grosjean (1992), Cook (1992, 1995), and others proposed that the traditional position on L2 competence, i.e., expecting multilingual and monolingual learners to achieve monolingual native competence, is a 'monolingual view of bilingualism.' As Edwards (1994) pointed out, a perfectly balanced bilingualism or multilingualism is exceptional. Most learners do not achieve native competence in a second or third language, and in some cases both teachers and learners view this as failure in the language acquisition process. This view is derived from the fact that only the norms of native speakers are considered, and that the needs of the learners and the ways that they are going to use the language are disregarded. In comparison to this 'fractional' view of an idealized form of bilingualism, Grosjean (1992) proposed a holistic view. Bilinguals seldom have balanced proficiency because they have developed communicative competencies in two languages according to the specific contexts in which they learn to use them. The language competence of bilinguals should not be regarded as simply the sum of two monolingual competencies, but rather should be judged in conjunction with the users' total linguistic repertoire.

Cook (1992) proposed the notion of 'multicompetence' to designate a unique form of language competence that is not necessarily comparable to that of monolinguals. According to Cook, second language users should not be viewed as imitation monolinguals in a second language, but rather they should be seen to possess unique forms of competence, or competencies, in their own right. Herdina and Jessner (2002) also adopted a holistic view of bilingualism and emphasized the fact that multilingual competence is dynamic rather than static.

Other specific theoretical proposals for multilingual processing have focused on the processing of the lexicon. For example, De Bot (2004) proposed a theoretical model that consists of three stores of information: conceptual features, syntactic procedures and form elements, and a language node that controls the use of the different languages. He concluded that there is no need to develop a specific model for multilingual processing, but rather the goal is to adapt the specific models so as to accommodate for more languages. Indeed, speech production in the different languages a multilingual uses may share most of the general characteristics of speech production in monolinguals and bilinguals, but necessarily presents more complexity and implies some specific characteristics derived from the interaction between different linguistic systems. The processes used in L3 acquisition may be very similar to those used by L2 learners, but, as Clyne pointed out, "the additional language complicates the operations of the processes" (Clyne, 1997: 113).

Contribution of Third Language Acquisition Research to Applied Linguistics

The study of third language acquisition makes an important contribution to research in applied linguistics because the process of acquiring a third language entails some specific characteristics that can help to understand the complex process of language acquisition in general. The diversity of third language acquisition and the interplay of combinatory possibilities in this process give rise to situations that are unique in language acquisition. Third language acquisition research is based on the theories and research methods used in second language acquisition, but can also contribute empirical data and theoretical proposals that are of interest to researchers working in other areas of language acquisition, and to applied linguists in general.

Acquisition of a third language has a great deal in common with second language acquisition (for example, in terms of research methodologies), but there is a need to conduct research specific to multilingualism in order to identify unique characteristics and operations that affect this process. Research that compares second language acquisition to third language acquisition is central in third language acquisition studies in order to identify specific and unique characteristics in the process of third language acquisition.

Another important reason to focus on the specific characteristics of third language acquisition is that research in this area brings together the disciplines

of bilingualism studies and second language acquisition research. These two areas have often ignored one another, the latter concentrating on the processes involved in the acquisition of a second language and the description of the resulting proficiency, and the former often concentrating on the effects of bilingualism on cognitive development. The study of the impact of bilingualism on third language acquisition brings these two traditions together.

Thomas of Erfurt (fl. 1300)

S Watanabe, Sophia University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Thomas of Erfurt probably obtained the degree of Magister in Paris, where Petrus Heliae had started philosophizing language, i.e., philosophical theorizing about language. Around 1300 he was Magister regens (principal) and rector at St. Severi School and St. Jacob School in Erfurt, Thuringia, Germany.

Owing to his logical studies on language such as *Novi modi significandi* and *Tractatus de modis significandi sive grammatica speculative,* he is regarded as one of the leading writers of the so-called 'Modists' school.' His *Grammatica speculativa* had been considered for a long time to be a work by Duns Scotus until Martin Grabmann (1922) proved it to be Thomas's lucubration. Martin Heidegger's *Habilitationsschrift* (1916) treated in fact Thomas's *Grammatica speculativa*. Thomas's other works include *Fundamentum puerorum*, an elementary grammar book in verse for didactic and mnemonic purposes, as well as commentaries on Porphyrius's *Isagoge* and others.

His definition of grammar has become a long-lived tradition in the history of grammar books in Europe: "*Grammatica est scientia docens nos recte scribere, recte scripta recte intelligere, recte intellecta recte componere, recte composito debito modo pronunciare*." These divisions of grammar came to be called orthographia, etymologia, diasynthetica, and prosodia, respectively, of which the most remarkable division is diasynthetica, i.e., syntax.

In the tradition of Latin grammar books during the Roman Age, syntax had tended to attract little attention. Latin being the native language of the Romans, their grammar books mainly treated accidence, i.e., how words should be inflected. In the Middle Ages, however, those whose native languages were not Latin began to use Latin as a kind of Koine of Western Europe with the result that syntax, i.e., how to make sentences of words without causing confusion, became more and more important. The Latin language of the Middle Ages, i.e., Medieval Latin, was the vehicle of scholasticism, a most delicate hair-splitting kind of thinking and discussing. In that kind of philosophy, syntax must be ruled by exact regulations, and these syntactical rules came to be equated with those of the human mind. This tendency was started in Paris, where Thomas studied, around 1150 by Petrus Heliae. Such philosophizing of language, which began with scholastic commentaries by Dominican monks on Donatus and Priscianus, can be said to have culminated in Thomas's *Grammatica speculativa*, and his contemporaries, such as Siger de Courtrai.

Their belief that there should exist only one *a priori* pure grammar common to all languages was more or less neglected for a long time, but Edmund Husserl (1913) showed that the ideal of *a priori* grammar has a solid claim and a certain extent of applicability. The return to this idea of intrinsic correlation between mind and grammar can be witnessed in Noam Chomsky's popularity after the dominant school of structural linguistics based on 'stimulus and response' lost its luster.

Thomas, John Jacob (ca. 1840–1889)

K W Lindley, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

Born in Trinidad in 1840, John Jacob Thomas is perhaps best known for his work *The theory and practice of Creole grammar*, a description of the French Creole of his home island that remained the benchmark study of the language until well into the 20th century. The accuracy and thoroughness with which he wrote his book earned him considerable praise during his lifetime, both at home and in Europe. His achievement is all the more remarkable in that he was not a native speaker of French Creole, having studied and acquired it upon assignment as a teacher to an area in which the

language served as the predominate means of communication. As a Black male of humble origins, he also garnered lasting admiration for his articulate, erudite response to a prominent White scholar's attack on West Indians of African descent.

Thomas received his education in one of Trinidad's ward schools and at the Woodbrook Normal School in the environs of Port-of-Spain, the island's capital city. In 1860 he was appointed the schoolmaster at Savonetta, a Patois-speaking community, and so set out immediately to learn the language of his students. (A native speaker of English, Thomas also acquired competency in Greek, Latin, French, and Spanish over the course of his lifetime.) In 1866, having scored first on newly established competitive civil service examinations, he was appointed to the office of the Receiver-General, and in 1869 was sent to Cedros as Clerk of the Peace. Thomas spent virtually his entire career in the employ of the Civil Service as an educator in various locations in central and southwestern Trinidad, and even lived and worked as a tutor in St George's, the capital of the island of Grenada, later in life. He also received appointments to the Education Board and to the council of Queen's Collegiate School.

The appearance in 1869 of Thomas's *Theory and practice of Creole grammar* earned him the respect of his contemporaries, including Trinidad's governor, Arthur Gordon, who introduced him to the British writer Charles Kingsley, a visitor to Trinidad in that same year. It was in part because of these connections that Thomas was able to travel to England in 1873, where his book had been widely acclaimed. He was received there as something of a celebrity, and delivered a paper entitled 'On some peculiarities of the Creole language' before the Philological Society of London.

In 1876 Thomas wrote *Froudacity* as a rebuttal to J. A. Froude's *The bow ofUlysses,* which attempted to justify a more stringent form of British colonialism in the islands based on what Froude proposed was the innate inferiority of West Indian Blacks. This work earned Thomas international recognition and established his reputation as a scholar of considerable ability. In the same year, he married Mary Ann Jane Regis in the Roman Catholic cathedral of Port-of-Spain.

Three years later, confined to his bed with rheumatism and partially blind, Thomas resigned his position and spent his convalescence translating from French to English *A history of Trinidad under the Spanish government*. After having largely recovered, Thomas was appointed headmaster of the San Fernando High School in 1883, where he was occasionally forced to defend his appointment against charges that he was not up to the job and was only given it because of his status as a freemason. In characteristically efficient fashion, Thomas drew a distinction between himself, a locally born man who, like his charges, was the product of an humble environment, and the formally educated outsider whose good intentions could not make up for his lack a common background with his students. In 1888, Thomas made the decision to live and work in Grenada, where he was serving as a tutor, just before his departure on a second trip to the United Kingdom. His intent during this journey was to prepare for a second edition of *The theory and practice of Creole grammar,* which would have compared the various creoles of the West Indies and other areas of the world. Although he managed to spend a period of time conducting research in the British Library, his health deteriorated considerably, and he was soon gravely ill. John Jacob Thomas died in London of tuberculosis on September 20, 1889.

Largely self-taught, Thomas holds a prominent place in Creole linguistics for his outstanding original contribution in the form of his book, *The theory and practice of Creole grammar.* He was the first black man, and one of the first linguists, to produce a Creole grammar, and for over 100 years his work was the authoritative description of Trinidadian French Creole. It is worth noting that his work, published in 1869, predates similar ones focusing on the grammars of Guyanese Creole (1872), Martiniquan Creole (1874), and Mauritian Creole (1880) (Gilbert, 1994: 4607). He was at the same time a pan-Africanist who was in many ways a precursor to the prominent figures of the black nationalist movements of the 20th century. His *Froudacity* continues to be praised by prominent scholars of Black Studies, such as Selwyn Cudjoe, who references Thomas's "audacity" in responding to such a prominent White intellectual, and C. L. R. James, who says that Thomas "overwhelmed" Froude (Smith, 2002: xii–xiii). In addition to Thomas's prominence as a linguist and Creolist, the scholar Faith Smith assigns him a place in history as "a late-nineteenth century pan-Africanist precursor of Marcus Garvey, a Caribbean anti-imperialist who is an important nodal point in a tradition stretching from Toussaint L'Ouverture to Fidel Castro, and a worthy competitor of White Victorian Intellectuals" (Smith, 2002: xv).

Mr. L. C. Thompson is a descriptivist and comparativist credited with contributions in Vietnamese and Salish (North American Indian). His scholarly career was cut short by stroke-induced aphasia at age 57.

Born on March 11, 1926, in Manchester, New Hampshire, Laurence Thompson spent his youth in New England. He studied French and Spanish at Middlebury College for two years, interrupting his college education to join the U.S. Army in 1945. He then returned to Middlebury and graduated *magna cum laude* in 1949. He pursued graduate studies in Russian language and Slavic linguistics at Yale, where he studied under Bloch (*see* **Bloch, Bernard (1907–1965)**) and Edgerton (*see* **Edgerton, Franklin (1885–1963)**), the latter serving as a role model for Thompson. His entry into the Vietnamese phase of his career was fortuitously prompted by the opportunity to join that fledgling areal program. His two years of field work in Vietnam resulted in the doctoral dissertation 'A grammar of spoken South Vietnamese' (1954). He taught the Vietnamese language at Yale for one year, and then spent two years at the U.S. Army Language School (later called the Defense Language Institute) at the Presidio of Monterey, California, where he supervised instruction in Russian and southeast Asian languages. *A Vietnamese grammar*, published in 1965, remains the standard work in Vietnamese analysis.

The Salish phase of Thompson's career spanned 9 years at the University of Washington (1957–1966) and 17 at the University of Hawaii (1966–1983). The fulfillment of a long-standing interest in American Indian languages, this phase coincided with the private and professional partnership of L. C. Thompson with Maranell Terry Thompson (born on April 1, 1927, in Colorado City, Texas). After their marriage in 1964, the Thompsons dedicated themselves to the documentation of Salish and other native languages of northwest North America. In a partnership in which L. C. Thompson did most of the synchronic and diachronic linguistic analysis and M. T. Thompson oversaw the details of organization and management, the Thompsons surveyed many of the two dozen lanuages of the Salish family, and together wrote grammars and dictionaries of Tillamook, Clallam, and Thompson as well as other linguistic documents. The Thompson team was instrumental in creating research opportunities that led to the preparation of dissertations on Lushootseed, Shuswap, Spokane, Colville (Okanagan), Saanich (Salish, Straits) Thompson (all Salish languages), and comparative Chemakuan (a neighboring family). After L. C. Thompson's aphasia, M. T. Thompson carried on with their work, preparing for publication their grammar and dictionary of Thompson and the ethnolinguistic component of the Thompson ethnobotany.

L.C. Thompson's deepest linguistic concerns centered on world view, as reflected in the characterization of Clallam (1971) as a language in which "the universe is viewed as autonomous and dynamic. Entities-persons and things are part of the general scheme, but are only incidentally responsible for situations which arise," or in his later claim (1976) that the morphemes of Salish languages carry values for "the degree of control that the agent exerts over the action, state, or process." The analog in his personal life was his discovery of his need to be in control, a recognition that M. T. Thompson says caused him hilarity, and that prompted him to dedicate the Thompson grammar to the therapist "without whom," he wrote, "none of this [work] would have been possible."

Thomsen, Vilhelm Ludvig Peter (1824–1927)

A Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Vilhelm Ludvig Peter Thomsen was born in Copenhagen, but he spent most of his childhood in the northern Jutland town of Randers, where he attended the Latin School. From there he returned to Copenhagen to attend university, and, like his compatriot Otto Jespersen with law and his Norwegian friend Johan Storm with natural sciences, a false start (in Thomsen's case as a student of theology) preceded his linguistic studies. He had a passion and a tremendous capacity for foreign languages, and he took every opportunity he could to learn new languages. His first publication, a comparative study of Hungarian, appeared in 1867. This, together with his doctoral dissertation of 1869 dealing with Finnish, meant that Thomsen was a pioneer in the field of Finno-Ugric philology. In 1869, as was quite typical for serious linguists at this time, he set off on an extended tour of Europe, to hear the languages and to hear the great European scholars of language. He returned home the following year and began working as a school teacher. This career was short-lived, and in 1875 he gained a permanent appointment at the university as extraordinary reader in comparative philology. Two years later he was promoted to an ordinary professorship in the same discipline.

The range of languages and linguistic topics on which Thomsen worked is impressive (see Sandfeld, 1983 for details), but his greatest achievement was the successful interpretation of the Old Turkish Orkhon inscriptions in 1893, which until then had confounded scholars. Turkish became Thomsen's dominant interest during the last decades of his life, but he found time for much else besides, including a history of linguistics (Thomsen, 1902). Despite the volume of his scholarly output Thomsen was also active as an administrator, serving as rektor of the university in 1902, and as president of the Danish Academy of Sciences in 1909.

Thought and Language: Philosophical Aspects

E Eaker, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

There is a veritable thicket of philosophical issues waiting to ensnare anyone who reflects on the relation between thought and language. The complexity of this thicket has been further enhanced by the fact that many philosophers have been preoccupied with trying to understand the nature and limits of human thought about the world we inhabit. In fact, philosophical interest in the relation of thought to the world has, to a large extent, motivated philosophical interest in language. For example, consider the proposal that our concepts and the basic structural features of our thoughts reflect the fundamental ontological categories 'out there' in the world. Some philosophers have proposed that by a careful study of language we can obtain a clearer grasp of the structure of thought and therefore a clearer understanding of what the world is like. Others have argued that the last place to look for metaphysical insight is language, thinking it to be a distorting mirror of the world. In addition to these broader metaphysical and epistemological questions – i.e., questions concerning what the world is like and what we can know about it – philosophical interest in language has also been motivated simply by an understandable fascination with the amazing human capacities for thought and language. It has been emphasized time and again that these capacities set human beings apart from the rest of the natural world.

Two of the main philosophical questions that have arisen regarding the relation of language and thought will be discussed here. First, philosophers have questioned the relative priority of thought and language: is thought prior to language (in some important sense to be defined) or vice versa? How one conceives of the relative priority of thought and language can affect how one approaches the second question: language and thought are both characterized by intentionality or 'aboutness'. When we think and speak, we are connecting with things in the world, and thinking and talking about them. Philosophers have sought to understand this aboutness of thought and language.

The Relative Priority of Thought and Language

Is thought prior to language? That is, is language merely a vehicle by means of which we express our thoughts? Some philosophers have argued (or merely assumed) that the capacity for linguistic expression is a capacity that allows us to communicate our thoughts and that we have an antecedent grasp on those thoughts. If so, one wants to understand what makes the structure of the natural languages well suited to expressing our thoughts. Are thoughts structured in a way similar to the languages that we use to express them? Is language a window onto the mind, so to speak?

Some have answered this last question affirmatively, but think that the reason the structure of human languages reflects the structure of human thought is because the capacity for language is **prior** to thought in some important sense. An extreme version of this view has been held by philosophers who are skeptical about the very existence of mental phenomena, such as thought. They point out that our tendency to attribute thoughts to other individuals depends largely on their capacity to use language. They argue that perhaps this linguistic behavior is all there really is to thought, properly so-called. Some have found this position too extreme, but have nonetheless stressed that thought, properly so-called, is not possible without the acquisition of a language and that the idea that language merely serves as the vehicle of thought is misguided. I describe a classic 'Cartesian' view of the primacy of thought over language and briefly sketch a thought-skeptical 'behaviorist' response to it, followed by a more nuanced view that recognizes the existence of thoughts, but argues that language is still prior to thought in an important sense. These issues are very much live ones in current research in linguistics, psychology, and philosophy departments, but to avoid some of the complexity and technical vocabulary of more current discussions, I present more classic loci of the above three positions.

The Cartesian View

The following passages from Descartes (1596–1650) represent commonly held views on thought and the relation between thought and language in the early modern and modern period. First, Descartes exhibits the perennial fascination with thought, and by extension language, as that which distinguishes man from beast. Discussing the possibility of automata constructed to look like and mimic the movements of animals and humans, Descartes writes:

> [I]f any such machines had the organs and outward shape of a monkey or of some other animal that lacks reason, we should have no means of knowing that they did not possess entirely the same nature as these animals; whereas if any such machines bore a resemblance to our

> bodies and imitated our actions as closely as possible for all practical purposes, we should still have two very certain means of recognizing that they were not real men. The first is that they could never use words, or put together other signs, as we do in order to declare our thoughts to others. For we can certainly conceive of a machine so constructed that it utters words, and even utters words which correspond to bodily actions causing a change in its organs (e.g., if you touch it in one spot it asks you what you want of it, if you touch it in another it cries out that you are hurting it, and so on.) But it is not conceivable that such a machine should produce different arrangements of words so as to give an appropriately meaningful answer to whatever is said in its presence, as the dullest of men can do. Secondly, even though such machines might do some things as well as we do them, or perhaps even better, they would inevitably fail in others, which would reveal that they were acting not through understanding but only from the disposition of their organs. (Descartes, 1999)

We see several themes in this passage. It is argued that what separates humans from the other animals is the capacity for thought and reason. This capacity underwrites the linguistic capacity of humans, whose linguistic behavior cannot be adequately understood as the predetermined, mechanically generated output response to various external stimuli. To describe the human linguistic capacity in such a mechanical way would be to miss the evident fact that humans, but not automata (or nonhuman animals), understand to a significant degree the external stimuli, are able to reason to an appropriate response, and, on making an utterance, mean what they say. Human language is thus fundamentally rooted in human reason, which is in turn an operation of the human mind. For Descartes, the mind is a distinct substance from the body and its workings cannot be explained by the mechanistic laws that govern bodies. Since nonhuman animals have no minds, they can be described in completely mechanistic terms. How can we know this to be the case? Descartes continues:

> Now in just these two ways we can also know the difference between man and beast. For it is quite remarkable that there are no men so dull-witted or stupid – and this includes even madmen – that they are incapable of arranging various words together and forming an utterance from them in order to make their thoughts understood; whereas there is no other animal, however perfect and well-endowed it may be, that can do the like. This does not happen because they lack the necessary organs, for we see that magpies and parrots can utter words as we do, and yet they cannot speak as we do: *that is, they cannot show that they are thinking what they are saying*. On the other hand, men born deaf and dumb, and thus deprived of speech-organs as much as the beasts or even more so, normally invent their own signs to make themselves understood by those who, being regularly in their company, have the time to learn their language. (Descartes, 1999)

Again, Descartes emphasizes the priority of thought to language when he characterizes language as essentially a vehicle of thought. What makes a string of noises a use of language is that it expresses what the speaker is thinking. Any real use of language requires that there be understanding, not mere parroting of sounds. Humans, but not magpies and parrots, produce words, and string them together into sentences in a certain way in an act intended to convey their thoughts. Mere strings of sounds, even word-like sounds, and sentence-like strings of them are meaningless unless produced with the intention of conveying thoughts. Descartes seems to presuppose that as humans – creatures with both mind and body – we are essentially endowed with the capacity for thought. If we are unable, for whatever reason, to learn or to produce the spoken or written language of our community, we will nonetheless have thoughts that we might wish to convey and will find some means for doing so.

Behaviorism

Some philosophers in the early 20th century questioned the rich ontology of mental phenomena that was taken for granted by Descartes. A particularly influential school of thought was 'behaviorism'. Not all behaviorists questioned the existence of unseen mental phenomena. Some were simply trying to demarcate what they took to be the appropriate data on which to base a science of psychology. Such 'methodological' behaviorists thought that scientific description of human psychology should focus exclusively on intersubjectively observable phenomena – in particular on behavior, including linguistic behavior. Such behaviorists had a proscription for scientific methodology in the field of psychology, but stopped short of metaphysical pronouncements. An 'ontological' behaviorist, on the other hand, is someone who wishes to give an analysis of mental vocabulary in terms of outwardly observable behavior, without reference to any phenomena that have those qualities thought to be characteristic of the 'mental' – e.g., being immaterial, inner, available as a result of immediate awareness or through 'introspection' and 'private' (i.e., inaccessible to someone else). An ontological behaviorist has a metaphysical bias against admitting the very existence of phenomena thus characterized and seeks to explain what mistakes we are making when we apparently make reference to

such phenomena. Behaviorism as a methodological thesis is not necessarily committed to such a strong metaphysical bias. Nonetheless, for all behaviorists there is a strong sense in which language is prior to thought: either mental vocabulary is analyzed in terms of behavior, in particular linguistic behavior, or, in the scientific description of human beings, it is abandoned in favor of description of behavior.

Sellars: Language as a Precondition for Thought

Wilfred Sellars provides a more nuanced view, avoiding a direct confrontation with our rather strong intuitions that there are mental phenomena, while at the same time explaining why language is indeed a necessary precondition for thought and not the other way around. In *Empiricism and the philosophy of mind*, he defends the following revised version of the classical analysis of our common sense conception of thoughts:

> [T]o each of us belongs a stream of episodes, not themselves immediate experiences, to which we have privileged, but by no means infallible, access. These episodes can occur without being 'expressed' by overt verbal behavior, though verbal behavior is – in an important sense – their natural fruition. Again, we can 'hear ourselves think', but the verbal imagery that enables us to do this is no more the thinking itself than is the overt verbal behavior by which it is expressed and communicated to others. . ..Now, it is my purpose to defend such a revised classical analysis of our common-sense conception of thoughts, and in the course of doing so I shall develop distinctions which will later contribute to a resolution, in principle, of the puzzle of *immediate experience*. But before I continue, let me hasten to add that it will turn out that the view I am about to expound could, with equal appropriateness, be represented as a modified form of the view that thoughts are *linguistic episodes*. (Sellars, 1997)

At the same time that Sellars wishes to defend a revised version of the view that there are 'inner' thought episodes, he also wishes to defend a revised version of the view that thoughts are linguistic episodes – the crude form of which is behaviorism. To explain what he means, Sellars introduces a piece of 'anthropological science fiction'. He imagines a stage of 'prehistory' in which humans are limited to using a 'Rylean language' – a language whose fundamental vocabulary is composed of terms for public properties and public objects located in space and enduring through time. It has resources for conjunction, disjunction, negation, and quantification; employs the subjunctive conditional; and allows for other 'looser' logical relations that are typical of ordinary discourse. Sellars asks: Would anything have to be added to the Rylean language to allow speakers of it to recognize and talk about themselves as beings that think (as well as having feelings, sensations, and perceptions)?

First, says Sellars, assume that they also have a way of making 'semantical' statements – i.e., statements about the meanings of the terms in their vocabulary, statements about what has been said by the assertion of a sentence, and a general ability to say that the assertion is true or false. If they have these resources, then they are arguably equipped to talk about thoughts – since thoughts share the same characteristics as bits of language. Just as we can say that when we use the expression 'tiger' we are talking about tigers, we can likewise claim to be thinking about tigers. Sellars proposes that we reverse the classical order of explanation and suppose "that the intentionality of *thoughts* can be traced to the application of semantical categories to overt verbal performances" (Sellars, 1997). Clearly, in order to support this proposal, Sellars must provide an account of the aboutness of linguistic expressions – what connects the term 'Tamela' with the individual, Tamela, whose name it is; what connects the term tiger with the species *Felis tigris*, and by extension with individual tigers; what connects the term 'hard' with that property that nails, concrete, and marble have, but which cotton and rabbit fur lack. Also, Sellars must provide this account without making reference either to a speakers' independent grasp in thought of some thing, kind, or property or to a speaker's intentions to refer to such a thing so grasped. Note that from a discussion of the relative priority of thought and language, we have moved into a discussion of the intentionality of thought and language. Sellars's view that language is prior to thought clearly constrains his explanation of the aboutness of thought and language.

Returning to Sellars's explanation of how speakers might come to talk about inner episodes such as thoughts, recall that Sellars's mythical Rylean language-speakers' capabilities include a description of public objects, properties, and relations and the ability to discuss the semantic properties of words and sentences. At some point, they will notice that their fellows exhibit intelligent behavior even though they are not making any assertions. This will lead them, says Sellars, to develop a theory according to which there are inner episodes that are the beginning of a process that usually, though not always, culminates in overt verbal behavior. The model for these episodes will be overt speech and thus what this rudimentary psychological theory will posit will be 'inner speech'. As it is inner speech, the semantical properties of

outward speech will be applicable to it, and so the Ryleans can talk of the inner episodes as having meaning and as being about various public objects. The term 'thoughts' could be introduced to name these episodes of inner speech. Insofar as the Ryleans had good reason to posit these thoughts (on the basis of observing intelligent behavior that is performed in silence), it can be assumed that they really do exist, with a nature to be further determined as the 'science' develops.

Two questions immediately come to mind about Sellars's account: One, if the overt verbal discourse is supposed on this theory to be the culmination of a process that begins with inner speech, i.e., thought, does this not take us back to the Cartesian view that overt linguistic behavior serves as a vehicle for the expression of thought? Two, if we are explaining the occurrence of overt linguistic behavior as the result of thoughts and we allow ourselves to talk about the semantic properties – the meaning and aboutness – of thoughts, are we not thereby analyzing the semantical properties of overt linguistic behavior in terms of the semantic properties of thought? In response to the first question, Sellars replies that, on the contrary, this theory "is perfectly compatible with the idea that the **ability** *to* **have thoughts** is acquired in the process of acquiring overt speech and that only after overt speech is well established, can 'inner speech' occur without its overt culmination" (Sellars, 1997; boldface added). In response to the second question, he writes, "It must not be forgotten that the semantical characterization of overt verbal episodes is the primary use of semantical terms, and that overt linguistic events as semantically characterized are the model for the inner episodes introduced by the theory" (Sellars, 1997).

Sellars continues with a description of how we come to self-ascribe thoughts. Sellars proposes that a speaker of the Rylean language, S, can be 'trained' on the basis of observing his own behavior, to say of himself that he is thinking 'p', just as a third party might say on the basis of S's behavior that S is thinking 'p'. According to Sellars, speaker S can eventually "be trained to give reasonably reliable self-descriptions, using the language of the theory, without having to observe his [own] overt behavior." With the spread of such reliable self-ascription of thoughts, the Ryleans will begin to talk of the 'privileged access' that each individual has to his or her own thoughts. Now, *prima facie* Sellars's story might seem to be exactly backward: after all, do we not think of thoughts as the sorts of things that we simply reflect on, things we introspect, and things we know the contents of? Is it plausible that speakers learn a language that has evolved with the expressive power to allow third-person ascriptions of thought, and that speakers then, by extrapolation, extend those concepts to themselves, self-ascribing thoughts and eventually becoming authoritative reporters of their own thoughts?

The problem with this type of objection to Sellars's myth is that it misses another key aspect of language, according to some philosophers, its essentially public and social nature. The public and social nature of language has been much emphasized by, e.g., Ludwig Wittgenstein, Paul Grice, and Saul Kripke. Sellars defends his picture by pointing out that it stresses the intersubjectivity of thought and the concepts that are used to describe such inner episodes, while not denying the fact that individuals do have privileged access to their thoughts and do make authoritative self-reports using these concepts. Of our use of concepts such as 'think', 'believe', and 'fear', in self-reporting, Sellars writes:

> [T]he reporting role of these concepts – the fact that each of us has a privileged access to his thoughts – constitutes a dimension of the use of these concepts which is *built on* and *presupposes* this intersubjective status. My myth has shown that the fact that language is essentially an intersubjective achievement, and is learned in intersubjective contexts – a fact rightly stressed in modern psychologies of language, thus by B. F. Skinner and by certain philosophers, e.g., Carnap, Wittgenstein – is compatible with the 'privacy' of inner episodes. It also makes clear that this privacy is not an 'absolute privacy.' For if it recognizes that these concepts have a reporting use in which one is not drawing inferences from behavioral evidence, it nevertheless insists that the fact that overt behavior *is* evidence for these episodes *is built into the very logic of these concepts*... (Sellars, 1997)

A Closer Look at the Relation between Thought and Language

We have seen only a sample of the various complex issues that arise when one considers the relative priority of language and thought. A few more questions might help to puncture the level of generality of the discussion thus far. Suppose with Sellars that mental concepts have "built into their very logic" that they are evidenced by overt behavior. What would this show about the primacy of language over thought? Sellars has told a tale in which thought emerges in individuals in a way that depends on their acquisition of a language. If he is right, then it would seem that he has given us a clear sense in which language is prior to thought. However, this is far from clear due to the sketchiness of Sellars's tale. Work on this topic by Vygotsky and, more recently, Andy Clark has seen the more detailed development of the view that although

we do not think in any particular language, the acquisition of a language provides the necessary scaffolding for thought. Some quite recent work by psychologists such as Elizabeth Spelke and Dedre Gentner also address these and related issues. (See, for example, Vygotsky, 1998, Clark, 2003 and Gentner and Goldin-Meadow, 2003.) Returning to Sellars, many questions remain untouched and suggest a much more complicated picture about the relation between thought and language, including the question of intentionality.

First, we might return to that part of Sellars's myth in which language begins to emerge in a community. Plausibly, the initial steps will involve the introduction of names for particular things, categories of things, properties of things, and relations that they bear to one another. How can this practice emerge if there is not an antecedent awareness on the part of the protolanguage users of individuals as distinct from one another, an antecedent awareness of ways in which things resemble or fail to resemble one another, and so on? That an expression can be introduced **for** some individual, collection of individuals, kind of substance, or property of things would seem to require an antecedent focus on it. This would suggest that the aboutness of linguistic items is not fundamental, but is instead derivative from the aboutness of such a prelinguistic focus of the mind.

Second, setting aside speculation into the origins of language, we can simply focus on individuals who are learning a language. In Sellars's favor, it does seem obvious that learning a language greatly enriches an individual's thought capacities. If I have no language, I am unlikely to have the concepts that would allow me to think: *The recent convictions of crooked CEOs who hold themselves above the law is symptomatic of the public's dissatisfaction with the current economic climate*. Nonetheless, consider the true language novice: Perhaps it is necessary for learning terms such as 'ball' and 'mommy', that a child can already discern in a rudimentary way an object from its surroundings, can distinguish one object from another, can distinguish himself from his mother, and can tell his own feet from toys in his crib. Perhaps some rudimentary conceptual abilities are preconditions for the acquisition of language. These questions are the focus of extensive empirical study and there remains a considerable amount of controversy over the role of language in concept formation and development.

Third, leaving aside the language learner, we can focus on the linguistically competent adult who asserts: *The man in the corner wearing the toupee is Janice's employee*. What makes it the case that this assertion is **about** some particular individual? Is it simply the fact that some man is standing in the corner indicated by the speaker and is the only such man wearing a toupee? In other words, does the definite description used, and the rules of language that govern how definite descriptions are to be used to refer to individuals by means of their properties, determine who is being referred to? Or are the intentions and mental focus of the speaker also important? Suppose there is a man in the corner but that he is not wearing a toupee. He is, nonetheless, the person to whom the speaker intends to refer. Can we make sense of the speaker having such an intention, independently of her use of a certain description? It would seem unintuitive to deny this. If we agree that it makes sense to say that the speaker **intends** to refer to a particular man, regardless of the description she uses, would we say that the speaker nonetheless **fails** to refer to that man, simply because that man does not fit the definite description *the man in the corner wearing the toupee*? In general, do linguistic expressions and the rules that govern them determine their own path to objects in the world or is the referential role of linguistic expressions parasitic on the more primitive aboutness of our thoughts?

All three of the above paragraphs concern the relative priority of thought and language when it comes to explaining the aboutness of our thoughts and of the 'referring expressions' in our language. But all three focus on a different stage in the development, acquisition, and use of language. Thus, not only the questions, but also the considerations that should be brought to bear in answering them will be different. Though this essay provides but a sampling of the variety and complexity of the issues concerning the relation between thought and language, it should help to explain why philosophers, linguists, and psychologists must spend as much time clearly articulating precisely what questions they are concerned with, as they do in looking for answers to them.

Introduction

Contemporary analytic philosophy of mind and language baffles many people, provoking the question: How do philosophers support the claims they make? And many people disapprove of the methods of contemporary linguistic theory, asking: How could these people be content to work with such unreliable data? The source of the reactions in both cases is the same – thought experiments. In contrast to the kind of experiments that are the central tool of science, both philosophers and linguistic theorists are quite happy to base their theories and claims on thought experiments.

A thought experiment is an exercise of the imagination. Specifically, it is imagining a scenario of some kind for some purpose. In contrast to what we might call a hands-on experiment, in which something in the real world is manipulated and observed, in a thought experiment we play around with aspects of a scenario in the imagination. (There is no perfect term to mark the contrast here; 'real experiment' and 'physical experiment' both beg the question. Some people hold that thought experiments **are** real experiments, of a kind, and, if the mind simply **is** material, then thought experiments are also physical experiments, of a kind.)

The kinds of scenarios imagined in philosophy are very different from those in linguistic theory and so is the putative point of the exercise. In philosophy, thought experiments are about complex situations and the point of the exercise is to determine whether the scenario or something contentious in connection with the scenario is possible. (Already here we see a large difference between the objectives of thought experiments and hands-on experiments: Thought experiments aim to reveal what is possible; hand-on experiments aim to reveal what is actually the case.)

In linguistic theory, thought experiments usually concern much smaller matters – strings of words – and the objective is to test intuitions of grammaticality or meaningfulness. The kinds of question asked are: Does this string sound grammatical? Could this string mean such-and-such in the imagined context?'

What baffles people about philosophers' use of thought experiments is that philosophers seem to believe that imagining some scenario could reveal

Thought Experiments

A Brook, Carleton University, Ottawa, Ontario, Canada

Introduction

Contemporary analytic philosophy of mind and language baffles many people, provoking the question: How do philosophers support the claims they make? And many people disapprove of the methods of contemporary linguistic theory, asking: How could these people be content to work with such unreliable data? The source of the reactions in both cases is the same – thought experiments. In contrast to the kind of experiments that are the central tool of science, both philosophers and linguistic theorists are quite happy to base their theories and claims on thought experiments.

A thought experiment is an exercise of the imagination. Specifically, it is imagining a scenario of some kind for some purpose. In contrast to what we might call a hands-on experiment, in which something in the real world is manipulated and observed, in a thought experiment we play around with aspects of a scenario in the imagination. (There is no perfect term to mark the contrast here; 'real experiment' and 'physical experiment' both beg the question. Some people hold that thought experiments **are** real experiments, of a kind, and, if the mind simply **is** material, then thought experiments are also physical experiments, of a kind.)

The kinds of scenarios imagined in philosophy are very different from those in linguistic theory and so is the putative point of the exercise. In philosophy, thought experiments are about complex situations and the point of the exercise is to determine whether the scenario or something contentious in connection with the scenario is possible. (Already here we see a large difference between the objectives of thought experiments and hands-on experiments: Thought experiments aim to reveal what is possible; hand-on experiments aim to reveal what is actually the case.)

In linguistic theory, thought experiments usually concern much smaller matters – strings of words – and the objective is to test intuitions of grammaticality or meaningfulness. The kinds of question asked are: Does this string sound grammatical? Could this string mean such-and-such in the imagined context?'

What baffles people about philosophers' use of thought experiments is that philosophers seem to believe that imagining some scenario could reveal

things of importance. Surely it takes 'real' experiments to do that. Researchers disapprove of linguists relying on their (smaller) thought experiments because whether a string seems grammatical or meaningful to someone or not seems to be an extremely insecure thread on which to hang anything, let alone something as complex and multitudinously vulnerable as a linguistic theory.

Philosophy and linguistic theory are not the only academic pursuits that make use of thought experiments. Physics, for example, is famous for its thought experiments, Schrodinger's cat and Galileo's tying a smaller and a bigger piece of matter together being two of the best known. Schrodinger argued, against the indeterminacy interpretation of quantum mechanics, that a cat in a box had to be in some determinate state even if we did not know what it was. Galileo argued, against the Aristotelians, that, if a smaller mass falls slower than a bigger one, then if we tie the two together the resultant mass ought to fall both faster and slower than the bigger of its two components by itself.

Sometimes psychological researchers use thought experiments, too. For example, some research into reasoning starts with getting the subject to do a thought experiment. The subject is asked to determine whether more words begin with *r* than end with it, for example, or to determine which of two alternatives is more probable. Presumably, the way in which subjects do this is by imagining something and then using what they have imagined to answer the question.

Big-scenario thought experiments play a larger role in philosophy than anywhere else, however; and small-scenario thought experiments play a larger role in linguistic theory than anywhere else.

Example Thought Experiments

We have already introduced examples of thought experiments from physics and psychology. To illustrate how thought experiments go in linguistics, take the kind of string that Chomsky made famous, for example, *colorless green ideas sleep furiously.* Is the string grammatical? Is it meaningful and, if so, what does it mean?

In philosophy, thought experiments go back to Plato's Myth of the Cave, if not earlier. Well-known recent ones include the Chinese room (Searle), Twin Earth (Putnam), and Mary the color scientist (Jackson).

Searle's Chinese room is the most famous thought experiment in recent history. Someone who knows no Chinese is put in a room. Sheets of paper with shapes on them come in through a slot. The person has an inventory of other shapes and a huge rulebook linking shapes to shapes. For each shape that comes in, she identifies and finds the linked shape(s) and shoves it (or them) out a second slot. Unbeknown to her, the shapes coming in encode questions in Chinese and the shapes going out are answers to these questions. What this is supposed to show, is that what the person who knows no Chinese does in the room, is all that a computer processing symbols by their physically detectable properties could do.

Twin Earth thought experiments go like this. Imagine a person here on Earth, Adam, and his completely identical twin, Twadam, on experientially indistinguishable Twin Earth. Adam and Twadam both use the word *water,* and they use it in situations that are experientially indistinguishable. Yet on Earth what is called *water* is H_2O and on Twin Earth it is XYZ. Does the word *water* as used by Adam and by Twadam have the same meaning? Evidently not. Yet everything in their heads is the same. Hence, in Putnam's memorable phrase, "meanings just ain't in the head" (Putnam, 1975: 227).

The thought experiment about Mary the color scientist goes like this. Mary is a wonderful color scientist. Indeed, she knows absolutely everything there is to know about color experience. Yet she has never seen a color. One day the blinders are removed and she sees color for the first time. It would seem that she would gain a new item of knowledge – what it is like to **experience** color. Hence, experience is not . . . (draw your favorite inference).

What are thought experiments like these meant to do? Indeed, why do serious adults indulge in such activities at all?

What Are Thought Experiments Supposed to Do?

What thought experiments are meant to do is different in each discipline that uses them. In physics, not only is the thought-experimental situation clear but its implications are clear, too, many of them anyway. The latter is notably not true of philosophers' thought experiments. In linguistics and psychology, the thought experiments are done by subjects, not by the researchers, and are meant to generate data, not sort out what is actual or possible with respect to data. Linguistic thought experiments generate data about the rules of syntax and meaning; psychologists' thought experiments generate data about how the mind works. (Brown, 1991, said that they are real experiments done in the mind, not thought experiments at all.) Philosophers' thought experiments do

not generate data and are meant to do something all by themselves.

Philosophers' thought experiments sometimes play a normative role, another thing that is not true elsewhere. Think again of thought experiments in reasoning research. Psychologists aim to find out how their subjects actually reason: what mistakes they make, what produces these mistakes, and so on. When a philosopher runs a thought experiment about reasoning, her interest is different, usually having to do with finding out something about what *good* reasoning consists of.

What people find baffling about philosophers and their thought experiments is that often they care more about possibilities than about what is actually the case. So long as a Chinese room is possible, Searle could not care less whether one had ever existed. The reason is that philosophers want to know what is possible and impossible, not (just) what is actually the case or not. The conclusion that we are meant to take away from the Chinese room experiment, for example, is that consciousness, understanding, and so on not only **are not** but **could not be** the manipulation of symbols by physically detectable properties.

Because thought experiments deal with what we take to be essential and distinctive about some kind of thing, they can reveal what our concepts for that kind of thing mean. Thought experiments cannot give us a final answer about what anything is like (believing the contrary was a key mistake of classical conceptual analysts). But they can give us a first answer – when we talk about consciousness or lexical meaning or . . . or . . . or . . . they can show us what we are talking about at that moment, even though we may revise the concept as we learn more (Jackson, 1998: 30–31; all this is similar to his notion of modest conceptual analysis, 1998: 43).

More particularly, thought experiments can reveal what *we* care about in connection with a concept. What matters to us about representation, for example? Well, one of the things that matters to us is its role in mistakes, in misrepresentation, and so on. For this task, determining what can and cannot be imagined with respect to things of the kind in question is actually **better** than determining what is actually the case with respect to things of that kind. Studying what is actually the case does not isolate what we take to be central to and characteristic of things of that kind. Determining what we can and cannot imagine with respect to things of the kind can do so.

Determining what we currently mean by a term and what matters to us about things of the kind named by the term may seem to be a rather modest contribution to intellectual life. Maybe; but it is also a vital one. Unless researchers are all talking about the same thing and take the same properties to be importantly distinctive of things of the kind, they risk talking past one another.

Philosophers' (and others') thought experiments can also play a role in hypothesis generation and, sometimes, in hypothesis elimination. Generating hypotheses is highly independent of data or any form of direct observation and/or manipulation of the world. Indeed, in hypothesis generation the imagination is the central player.

The hypothesis-generating function of thought experiments shows us one way in which they differ from hands-on experiments. Think of a possibility-space. Hands-on experiments uncover which of the possibilities in that space are actually the case. By contrast, thought experiments do two things. First, as we have seen, they help us forge conceptual tools for identifying and reidentifying items in the possibility-space. (We might call this their conceptual analytic role.) Second, they help us to identify possibilities, to generate ideas, concerning what might be going on in the space we are investigating. They give us new ways of picturing the phenomena under investigation. (We might call this their hypothesis-generating role.)

The idea that philosophers' thought experiments can also play a role in hypothesis elimination is more controversial. Thought experiments in linguistic theory and psychology clearly play this role The same is true of thought experiments in physics: Galileo meant to eliminate an hypothesis of Aristotelian physics, and Schrodinger meant to eliminate an hypothesis in quantum mechanics. How? The story may go like this. When thought experiments sort out a possibility-space, revealing the real possibilities and eliminating the merely putative ones, they also eliminate hypotheses. There is no reason why thought experiments in philosophy cannot play a similar role. However, they seldom are as clear or uncontroversial as thought experiments in other areas.

How thought experiments work is a complicated and controversial topic, but compare them to proofs in mathematics. Mathematical proofs are generally derivational: To justify a proposition, we show that it can be derived from well-accepted axioms using well-accepted rules. Thought experiments are not like this. They display something to us, something that was obscure or masked and that can be made clearer by imagining the indicated situation. (Because the objects and at least most of the relationships thus imagined are recalled from memory, memory based

on earlier experience, note too that thought experiments have an empirical element.)

To sum up, thought experiments are quite different from hands-on experiments. However, they play a role in hands-on experiments, generating concepts with which to do them and hypotheses for them to test. They can also play a role in eliminating hypotheses.

Thumb, Albert (1865–1915)

M Pierce, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Albert Thumb was one of the most important scholars of Greek of his time. Born in Freiburg im Breisgau in 1865, Thumb was a student of Karl Brugmann, who had a major impact on his scholarly career. In 1888 Thumb completed a doctorate in Strassburg, with a dissertation on aspiration in Greek, and then pursued his studies further in Munich and Greece. Thumb eventually returned to Freiburg as a *Privatdozent*, remaining there until 1901, when he accepted a position in Marburg. He left Marburg for Strassburg in 1909, and died in Strassburg in 1915, while holding a professorship of Indo-European linguistics there.

Thumb is best known for his work in Greek. He revised the Greek grammar of his teacher Brugmann (Brugmann, 1913), prepared a substantial handbook of Greek dialectology (Thumb, 1909), and published extensively on various questions of Greek linguistics and philology, including Greek inscriptions, ancient Greek prosody, the development of the Greek pronominal system, and Greek loanwords in Albanian and Armenian. Thumb's most lasting contributions to Greek linguistics lie in his work on Modern Greek. He published a number of books in this area, including two handbooks, the first of which was eventually translated into English (Thumb, 1910, 1912, 1915). Thumb was one of the few Indo-Europeanists of his day equally adept at Modern and Ancient Greek, a fact reflected in his publications. Thumb was also a skilled Indologist; he taught Indological courses in Marburg and also authored a handbook of Sanskrit that became a standard work in the field (Thumb, 1905). Finally, Thumb worked on a number of miscellaneous topics, ranging from the etymology of the Gothic word for 'shirt' to the psychology of language, especially regarding its possible relation to, and uses in, philology. Although many of his shorter works have been forgotten, his outstanding handbooks have made a place for him in Indology and classical studies even today. (See Hatzidakis, 1916 for an evaluation of Thumb's work and Anonymous, 1922 for a listing of his publications.)

on earlier experience, note too that thought experiments have an empirical element.)

To sum up, thought experiments are quite different from hands-on experiments. However, they play a role in hands-on experiments, generating concepts with which to do them and hypotheses for them to test. They can also play a role in eliminating hypotheses.

Thumb, Albert (1865–1915)

M Pierce, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Albert Thumb was one of the most important scholars of Greek of his time. Born in Freiburg im Breisgau in 1865, Thumb was a student of Karl Brugmann, who had a major impact on his scholarly career. In 1888 Thumb completed a doctorate in Strassburg, with a dissertation on aspiration in Greek, and then pursued his studies further in Munich and Greece. Thumb eventually returned to Freiburg as a *Privatdozent*, remaining there until 1901, when he accepted a position in Marburg. He left Marburg for Strassburg in 1909, and died in Strassburg in 1915, while holding a professorship of Indo-European linguistics there.

Thumb is best known for his work in Greek. He revised the Greek grammar of his teacher Brugmann (Brugmann, 1913), prepared a substantial handbook of Greek dialectology (Thumb, 1909), and published extensively on various questions of Greek linguistics and philology, including Greek inscriptions, ancient Greek prosody, the development of the Greek pronominal system, and Greek loanwords in Albanian and Armenian. Thumb's most lasting contributions to Greek linguistics lie in his work on Modern Greek. He published a number of books in this area, including two handbooks, the first of which was eventually translated into English (Thumb, 1910, 1912, 1915). Thumb was one of the few Indo-Europeanists of his day equally adept at Modern and Ancient Greek, a fact reflected in his publications. Thumb was also a skilled Indologist; he taught Indological courses in Marburg and also authored a handbook of Sanskrit that became a standard work in the field (Thumb, 1905). Finally, Thumb worked on a number of miscellaneous topics, ranging from the etymology of the Gothic word for 'shirt' to the psychology of language, especially regarding its possible relation to, and uses in, philology. Although many of his shorter works have been forgotten, his outstanding handbooks have made a place for him in Indology and classical studies even today. (See Hatzidakis, 1916 for an evaluation of Thumb's work and Anonymous, 1922 for a listing of his publications.)

Thurneysen, Rudolf (1857–1940)

S C O'Rourke, Yale University, New Haven, CT, USA

© 2006 Elsevier Ltd. All rights reserved.

Rudolf Thurneysen, an Indo-Europeanist whose work in linguistics and philology was centered around Celtic and Italic, was born on March 14, 1857 in Basel, Switzerland. For years he stood as one of the most preeminent scholars of Old and Middle Irish language and literature. Beginning in 1875, Thurneysen studied comparative Indo-European (especially Celtic and Romance) philology at the universities of Basel, Leipzig, and Berlin under such luminaries as Jakob Burckhardt, August Leskien, Friedrich Nietzsche, Ernst Windisch, and Heinrich Zimmer. In 1879 Thurneysen earned a doctorate from Leipzig for his dissertation on Latin verbs. He studied further under the likes of Henri Gaidoz at the École des hautes études and the Collège de France in Paris and at Basel before completing a Habilitation at Jena (Germany) in May 1882.

Thurneysen was Privatdozent (external lecturer) of Celtic and Romance Philology at Jena until mid-1884, when he was appointed the equivalent of associate professor in the same fields. From early 1887 through March 1913, Thurneysen was Professor of Comparative Linguistics at Freiburg im Breisgau, the successor to Karl Brugmann – who had left for Leipzig – and from April 1913 until he received emeritus status in September 1923 (at his own request), Thurneysen was Professor of Indo-European Linguistics and head of the linguistics department at Bonn. In 1911 and 1929 Thurneysen offered seminars in Dublin at the School of Irish Learning and the Royal Irish Academy, respectively.

In 1909, Thurneysen introduced his authoritative *Handbuch des Alt-irischen*, later translated into English as *A grammar of Old Irish* and *Old Irish reader* and, in its various forms, still the standard reference work for students of Old Irish after nearly a century. Throughout his life he made significant contributions to the field of linguistics with regard to Germanic, Italic (especially Latin and Romance), and all of the then known Celtic languages. Thurneysen considerably advanced the understanding of early Irish metrics and of stress and the complex verbal system in Old Irish. Thurneysen's Law, which relates to the voicing of certain fricative sounds in Gothic, is attributed to him as well.

Thurneysen also published widely on various topics concerning early Irish literature and often served as a translator and editor of texts in that area. From just before the outset of his retirement in 1923 until mid-1940, Thurneysen served as a collaborating editor of the *Zeitschrift für celtische Philologie*, in which appeared much of his work on the subject of early Irish law that captivated him for the last 20 years or so of his life. He died on August 9, 1940 in Bonn, leaving his wife since 1893, Elisabeth (née) Kriebel, and four daughters, Barbara, Elisabeth, Hedwig, and Marianne.

Tibet: Scripts

M A Thompson, Indiana University, Bloomington, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Tibetan scripts derive from a late Brahmi script, probably Siddhamatrka, from the Gupta period. There are several styles of Tibetan script proper that were devised by the 8th century and have remained in use until the present day. Traditionally, Tibetan script was considered to have been introduced by Buddhist monks sent to India during the reign of the Tibetan king Srong-btsan sgam-po (reigned 627–650), but the native Bon tradition records a lengthier process, corroborated by early monuments written in Tibetan script that do not mention Buddhism (Beyer, 1992: 40–41; Narkyid, 1983: 207–220). The orthography was reformed and codified early in the 'Second Conversion' to Buddhism of the 10th and 11th centuries; the reformed orthography (referred to as Literary Tibetan) shows little dialectal variation apart from morphosyntactic ones. The major offshoot of Tibetan script is 'Phags-pa script, devised between 1264 and 1269 by the lama 'Phags-pa Blo-gros rgyal-mtshan, head of the Sa-skya-pa sect ('Gray Earth,' named after the head monastery, and colloquially referred to as the 'Flower Hats'), at the behest of the Mongol Great Khan Khubilai to serve as a universal script for the major languages of his empire (Chinese, Mongolian, Tibetan, and Uighur [Uyghur]) and for Sanskrit. Although this script (called 'Phags-pa script,' 'quadrilateral' or 'square script,' or 'new Mongolian script' in various languages) was used in the higher levels of imperial administration, it did no displace any of the rival scripts and after the end of the Yuan dynasty in 1368 was only used ceremonially among the Mongols; as a widely used script it survived only in parts of Tibet (van der Kuijp, 1996: 437).

Principles of Tibetan Script

Tibetan script adapted 25 consonant signs and four vowel signs from Brahmi script; the forms used are identical to those in an inscription from Golapur dated c. 500 (Beyer, 1992: 41). The varieties of Tibetan script differ in the extent to which they write bars at the tops of letters: *dbu can* 'headed' script (the basis for the printed letters familiar in the West) writes horizontal bars as part of the letters; the various styles *of dbu med* 'headless' script lack

them. (Unlike Devanagari, Tibetan script never joins letters with horizontal bars.) As in Devanagari, each consonant sign indicates an inherent *a* unless position or vowel sign indicates otherwise (see Table 1). In addition to the letters borrowed from Brahmi, Tibetan script contains modified forms of the palatal series to write dental affricates; there are also two letters that are often taken to indicate a vowel at the beginning of the syllable, *a-chen (a-čʰen)* 'large *a*' (from Brahmi) and '*a-chung ('a-čʰuŋ)* 'small *a*' (of uncertain origin). The former indicated a syllable-initial glottal stop, while the original value of the latter is disputed: In later dialects it is realized as zero, prenasalization, or a glottal or velar/uvular consonant, depending on environment. Based on Tibeto-Burman comparanda, Matisoff (2003: 116) reconstructed it as a nasalized glottal stop in early Old Tibetan, which is followed here, though this value should not be assumed for Literary Tibetan. In addition, this letter serves three other functions: (1) it serves as a vowel support for the offglide of diphthongs resulting from the diminutive suffix *-u* and (in modern Tibetan) case endings in *-i*; (2) in ambiguous sequences of two consonant signs, '*a-chung* is placed after the second consonant if it is followed by *a*; (3) in transcriptions of Sanskrit, '*a-chung* is written subscript to indicate a long vowel.

However, because Old Tibetan possessed a much richer inventory of consonant clusters than did Sanskrit or contemporary Indic languages, Tibetan script indicated syllable boundaries explicitly by a raised dot *(bar tsheg* 'intermediate dot'), thereby obviating the need for most conjunct letters (which often cross syllable boundaries in Indic orthographies) or the *virama* (used to indicate a syllable-final consonant). The Old Tibetan syllabic nucleus consisted of a vowel (*a*, *e*, *i*, *o*, *u*); diphthongs were rare and occurred only in open syllables. Syllables could have codas of one or two consonants and onsets of up to four consonants. In the coda slot only voiced stops (*b*, *d*, *g*), nasals (*n*, *m*, *ŋ*), liquids (*r*, *l*), and *s* could occur; complex codas consisted of a grave (labial or velar) consonant followed by *s* (and in Old Tibetan by *d*, called *da-drag* 'heavy *d*', which was in complementary distribution with *s* but was lost by the time of Literary Tibetan). Coda consonants are written to the right of the letter supporting the vowel.

All consonants can occur in simple onsets; one consonant can follow and two can precede the simple onset slot (the 'initial'), with co-occurrence restrictions based largely on the value of the initial. In general, Tibetan script indicates more complex onsets by appropriate modifications of the letter for the initial (the 'central position'): letters for consonants in the slots immediately preceding and following the initial are superfixed and subfixed to the central letter (only superscript *r* and subscript *r*, *y*, and *w* are true conjunct letters); consonants in the first onset slot ('prefix consonants,' which seem to have been extrasyllabic) are written to the left of the central letter. That the distinction between initials and prefixed letters was phonologically real is shown by, for example, the regular developments of *g.y* and *gy*: *g.yag* → *yág* ~ *yáà* 'yak' vs. *gyag* → *gyàg* ~ *jàg* 'destroying'. Vowel signs are written either above (*e*, *i*, *o*) or below (*u*) the central letter, including any adscripts. However, the correspondence between onset slot and position in the written syllable was not observed for all onsets of two or three consonants; thus, *r*, *l*, and *w* preceded by other consonants were always written subscript even when they appear to have occupied the initial slot. This mismatch has complicated the rules for deriving the modern pronunciation from the spelling. (Thus, subscript *l* acts as an initial except when subscript to z: *zla-pa* → Lhasa *dàwa* 'moon', cf. *sla-po* → Lh. *lábo* 'thin, weak'.)

The letters *r*, *l*, and *s* can be superscript, and *r*, *y*, and *l* are the major subscript letters. The relatively rare subscript *w* (*wa-zur* 'corner *w*') appears in some words to have reflected a rounding of the preceding consonant that has left no traces in the modern dialects, but in other words seems to have served only to distinguish homophones; it may also occur subscript after subscript *r*. The letters *b*, *d*, *g*, *m*, and '*a-chung* can occur in the leftmost position, though only *b* co-occurs with superscript letters. Each of these letters could co-occur with a limited subset of possible initials, usually natural classes (for example, subscript *y* can only follow velar stops and the labial nasal and stops – dentals followed by *y* had developed into the palatals before the adoption of writing); moreover, not all superscript and subscript letters could co-occur (*r* cannot be both superscript and subscript, for example, and superscript *l* cannot occur with a subscript letter; Beyer, 1992: 68–89). Restrictions on which initials can occur with other onset consonants can be found in most grammars of Literary Tibetan (e.g., Goldstein, 1991: 23–27).

Modern Pronunciation Rules

The rich variety of consonant clusters in Old Tibetan was drastically reduced through massive cluster simplification, leading to the development of tones and a wider range of vowels. Broadly speaking, this process has proceeded furthest in the central Tibetan dialects, which allow no onset clusters and only nasal codas (and *r*, *b* and *g* in many varieties). Because of its international prestige, discussion of developments will be limited to the Lhasa dialect, though other

May the supreme jewel Bodhicittas
That have not arisen, arise and grow;
And may that which has arisen not diminish
But increase more and more.

From Shantideva (Slob-dpon-shi-ba-lha), *Bodhisattvacharyavatara* (*sPyod-'jug, The Bodhisattva's Way of Life*), early 8th century CE. Text and translation provided by Yangbum Gyal.

[1] Tibetan for *Bodhicitta* 'Enlightenment Mind.'

Figure 1 Sample of Tibetan script.

dialects are of greater philological interest (such as Amdo, spoken in northern Qinghai, which is the source for most Tibetan loanwords into Mongolian and other Inner Asian languages).

In general, initials retain their Old Tibetan places of articulation unless followed by the subscripts *r* and *y*; the former has created a series of retroflex stops or (in elegant Lhasa Tibetan) affricates (from labials, dentals, and velars) and the latter palatals (the labials developed into palatal affricates, the velars into palatalized velars or palatal stops). Pre-initial consonants, on the other hand, affected the voicing and manner of initials. Changes in voicing induced by pre-initials interacted with the loss of a three-way distinction in voicing in the obstruents to create a system of high and low tones; in modern central dialects the effects of pre-initial consonants are best described by the resulting tonal categories and voicing (Goldstein, 1991: 3–5, 23–27; Miller, 1956: 6–15). At the other end of the syllable, coda consonants affected the preceding vowel as follows: (1) the dentals *d*, *n*, *s*, and *l* fronted preceding vowels ($u \rightarrow$ *ü*, *o* $\rightarrow$ *ö*, *a* $\rightarrow$ *ɛ*); *b* raised *a* to *ə* and *r* lowered *o* to *ɔ*; (2) vowels were lengthened preceding *l*, *d*, *s*, *n*, *r*, and *g* (unless the variety preserved the last two); (3) vowels before *s*, *d*, and *g* took a low tone to yield falling high and low tones. In final clusters, the final *s* was lost without affecting the rest of the syllable except for minor tonal effects on preceding nasals (Goldstein, 1991: 10–14). The most elegant forms of Lhasa Tibetan retain only nasal codas; other varieties of central Tibetan retain final *b* and, more variably, *g* and *r*. (Beyer, 1992: 27–28).

With cluster simplification there was a concurrent process of lexicalization of earlier collocations as disyllabic words marked by numerous lexically based phonological rules:

1. Pre-initials of the second morpheme were resyllabified as the codas of preceding open syllables if the word was lexicalized before the loss of pre-initials; in this case, '*a-chung* developed into a nasal homorganic with the following consonant. Thus, *rdo-rje* $\rightarrow$ *dor-je* 'thunderbolt, *vajra*; diamond', which was borrowed into Mongolian as *dorji*; similarly, the negative verbal particle *mi* was lexicalized with a following existential verb '*dug* quite early, giving the modern pronunciation *min-dug*. Similarly, codas of first syllables are often preserved in disyllables, but there are many exceptions depending on the looseness and the date the word was lexicalized.
2. The morphemes in lexicalized collocations display tone sandhi.
3. A system of vowel harmony based on the height (high versus nonhigh) of the second vowel has developed.
4. The voicing of some medial obstruents changed (Goldstein, 1991: 27–29).

See Figure 1 for a sample of Tibetan script.

[a] Not used in Mongolian words.
[b] Used in Chinese words.
[c] The signs ⟨γ⟩ and ⟨•⟩ probably indicated a voiced uvular stop and fricative in the early 13th century or before; later they lenided to a voiced uvular fricative and zero. (Poppe, 1957: 19–34; van der Kuijp, 1996; 437–441; Miller, 2002: 179–205.)

Vowel

	Initial	*Non-initial*		*Initial*	*Non-initial*
a		—	ä		
e			ö[d]		
i			ü		
o[d]			ɨ		
u					

[d] A vertical medial line is used to link these vowel signs to a following tautosyllabic consonant.

Mongolian diphthongs (non-initial)

	ayi	[e]	eyi		oyi
[e]	ei		ui		üi

[e] Generally *eyi* (*äyi*, occasionally *eyi*) is used in non-final position, *ei* (*äe*) finally. (Chinese diphthongs are written *ay*, etc.)

Conventions for Foreign Words

Special forms of the Tibetan letters are used to transcribe Sanskrit. Retroflexes are written with the mirror image of the corresponding dentals, and certain clusters foreign to Tibetan are written with adfixed letters. Long vowels are indicated by a subscript ‘*a-chung*. Voiced aspirates are written with *h* subscript to the corresponding voiced consonant. Finally, symbols for *visarga*, *anusvara*, *anunasika*, etc., are also used in Tibetan without change. Foreign sounds in other languages are generally transcribed with sequences of Tibetan letters; thus, *f* in English and Chinese loanwords is written as *h* with a subscript *w*. Especially noteworthy are the conventions for writing Turkic front rounded vowels, for they were carried over into ‘Phags-pa script: noninitial rounded vowels were written with subscript *y* (continued by the ‘Phags-pa symbol for *ä*) and the corresponding unrounded vowel (thus, *kyu* indicated *kü*); initially, they were supported by *a-chen*. This system continues the Brahmi system for the noninitials, but modifies that for initials (in which *ä*, *e*, *ö*, and *ü* were written *aya*, *eya*, *oya*, and *uyu* respectively) (Ligeti, 1961: 210–211).

‘Phags-pa Script

In order to create a script that could be used to write all the major languages of the Mongol empire, the ‘Phags-pa lama provided symbols for all the phonemic distinctions in the languages in question, from

'Now, in that case, in accordance with earlier edicts stating that they [Buddhist, Taoist, Christian, and Muslim clergy] are to pray to Heaven and offer benedictions while not being subject to any corvées or taxes apart from the land and commercial taxes, we have issued a writ to be retained. Messengers are not to stop at their temples and dwellings. They must not take relay horses or provisions. They must not seize or appropriate their lands, waters, or anything else.' (Edict of Mangala, 1276, lines 6-20 of the Mongolian text. Fair copy by author. Chevannes, Plate XIX; Poppe 46-7).

Figure 2 Sample of 'Phags-pa script.

which a given language would be written with a subset of the symbols chosen for the best phonetic fit, which is much the same principle as that of the IPA; thus, while the script can indicate a three-way voicing distinction for stops and affricates, languages such as Mongolian or Uighur would ideally use only two of the series, chosen to best indicate the degree of voicing and aspiration. The script is thus of extreme interest to the historians of these languages, for it provides a broad transcription of the prototypical values of the target phonemes. However, while the script is conventionally dated to between 1264 and 1269, it likely incorporated earlier Tibetan and Brahmi systems for writing other languages; in addition, the native conventions for each script were often followed without regard for allophonic variation or later changes. Thus, the interpretation of 'Phags-pa script for a given language requires some care.

As in Tibetan, 'Phags-pa script is largely alphabetic; consonant signs have inherent *a* in the absence of

another vowel sign. Most of the letters are taken from Tibetan script but the organization of the script derives from Uighur-Mongolian, and the signs for many non-Tibetan sounds follow Brahmi conventions. The script is oriented top to bottom and left to right, with the characters for each syllable joined in a square. Generally the script assumes CV(C) syllable structure; Tibetan words with consonant clusters are written as in Tibetan. Vowel signs follow the first full consonant sign, with special signs for initial vowels (see Table 2).

The approximate phonetic values of most 'Phags-pa signs are clear, but those of the signs herein transcribed • and γ are still debated. The former derives from Tibetan '*a-chung*, whose value at the time the script was devised is unclear, while the latter was used particularly for Middle Mongolian γ, which has generally been lost intervocalically in the modern dialects to yield long vowels. Moreover, their interpretation depends crucially on the extent to which Uighur-Mongolian conventions were followed in 'Phags-pa. The values accepted here must be taken as having been adapted to the phonemic system of the target language, with interference from native orthography. Thus, they are close to the values found from internal reconstruction of early Mongolian as preserved in Uighur-Mongolian script; however, transcriptions of Mongolian in Arabic and Korean scripts vary extensively in the values indicated for these sounds: zero in the Mongolian dictionary of the *Muqaddimat al-Adab* (Poppe, 1927: 22); zero, *g* (rare), or *w* in the Istanbul manuscript of the *Shamil ül-lugha* (Ligeti, 1964: 113–119); zero, *h*, *w*, and *g* in the Leiden manuscript of a Turko-Mongolian lexicon (Poppe, 1927: 1017–1024); and zero between like vowels and γ between unlike vowels in Korean transcriptions of Middle Mongolian (Miller, 2002: 200n40). Besides the fact that these transcriptions postdate the creation of Mongolian script by well over a century, there is probably dialect variation involved. Similarly, • is used for phonemic γ in Old Mandarin, realized variously in different environments (Miller, 2002: 190–196).

Because the most significant texts in 'Phags-pa script are in Chinese or Mongolian, the conventions for these languages are indicated in Table 2. It is important to note that Mongolian is typically written in 'Phags-pa script following the conventions of Uighur-Mongolian script. Thus, vowel harmony is usually indicated by the choice of velar sign, and in other cases is often indicated only in the first syllable (see Figure 2).

Tibetan

P Denwood, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Tibetan comprises a multiplicity of regional spoken dialects, and a standardized written language (Classical Tibetan) which is the vehicle of a major civilization whose main religion is Buddhism. There are also several modern regional written languages.

Geography, Affiliation, and History

Tibetan is spoken in the Tibetan Autonomous Region of China, and in adjoining high-altitude

parts of Bhutan, India (Ladakh in Kashmir and parts of Himachal Pradesh), Pakistan (Baltistan), Nepal (Mugu, Dolpo, Mustang, Solu Khumbu), Burma, and the Chinese provinces of Yunnan, Sichuan, Gansu, and Qinghai. Estimates of the number of speakers range from about three to seven million. It is also used as a religious language by Mongols in the Republic of Mongolia, Inner Mongolia (China), and Russia (Buriats and Kalmucks), and by members of some ethnic groups in Nepal, including Newars and Tamangs, and other parts of the Himalayas. It is usually reckoned to be a member of the Tibeto-Burman language group, which, with the Karen and Chinese groups, forms the Sino-Tibetan family, though some scholars have cast doubt on this affiliation, citing parallels with Indo-European.

The Tibetans emerge into history in the 7th century AD. It is from that time also that their alphabetic writing system, based on a model of Indian origin, is alleged to date. The earliest datable example of the language is probably an inscription on a stone pillar in Lhasa dating from about 760 AD. Although originally often used for administrative purposes, since the 10th century Classical Tibetan has been closely associated with Buddhism, having been used to translate a vast range of literature, mostly from Sanskrit. There is also an indigenous literature, which was also almost entirely religious until the mid-20th century. Since that time the nonreligious genres of journalism and other 'nonfiction' have also flourished, and since the late 20th century also novels, short stories and poetry.

The spoken dialects have usually remained unwritten. Poorly recorded from premodern times, they have often developed separately from the written language and from one another. To ease the consequent difficulties of communication, several of the spoken dialects have come to be used as *lingua francas*: Lhasa Tibetan over the Tibetan Autonomous Region and among the exile community; Dzongkha in Bhutan, Leh Ladakhi in Ladakh and Amdo Khake (Amdo) in Qinghai and Kansu. While parallel modern regional written languages have also been developed (see below), the gap between spoken and written forms of the language remains wide.

Grammar

Words

A Tibetan word (phonologically defined) comprises a noun, verb, or adjective constituent, with or without one or more particles. A noun constituent may be polysyllabic, while verb and adjective constituents are all monosyllabic. Many verbs have variant forms ('stems' or 'roots') corresponding to tense/aspect differences. Other parts of speech are invariable, apart from sandhi variation with suffixed or prefixed particles. Particles express noun case categories and adjectival degree, mark the ends of subordinate clauses, and establish verb tense/mood/aspect categories. Most particles are suffixed, though a few negative, dubitative, or interrogative ones are prefixed. There are also many phrasal nouns, verbs, and adjectives comprising two or more words. Particles are subdivided into noun, verb, and adjective, according to which type of word they occur in. A few particles can stand as separate words.

Noun Phrases

The order of elements in the noun phrase is: (1) head (noun), (2) epithet (adjective), (3) deictic (noun), (4) numerator (particle), (5) case marker (genitive, subject-marking, instrumental, dative-locative, ablative, comparative or adverbial particle).

Verb Phrases

In Classical Tibetan, a verb paradigm may have from one to four stems, and sometimes alternative forms for the same stem, e.g., the verb *seize* (shown here in transliterated Tibetan spelling):

present	past	future	imperative
'dzin./zin.	*bzung./zung.*	*gzung.*	*zungs.*

A few verbs have suppletive paradigms with stems drawn from etymologically different verbs.

Modern spoken dialects show a reduction in the number and variety of verb stems; for example in the Lhasa dialect, for most speakers no verb has a separate future stem and many verbs have been reduced to a single stem: the equivalent of either the present or past of the classical language. More than compensating for this reduction has been a great increase in the use of verb particles and auxiliaries to express a complex mix of person, tense, aspect, mood, and evidential and judgmental modality systems. In many dialects there is also an unusual system of what may be termed 'viewpoint' – self-centered vs. other-centered – in which there is concord between the verb phrase and the speaker, who may or may not correspond to one of the arguments of the clause.

Verbs may be divided into two types: verbs of being (also used as auxiliaries) and lexical verbs. Verbs of being participate obligatorily in the grammatical systems of viewpoint and evidential modality. Lexical verbs are of two types, which determine their participation in the systems mentioned: 'intentional,' where the action is under voluntary control, and 'unintentional.' The majority pattern of the lexical verb phrase is: (1) lexical verb stem, (2) linking

particle, (3) polar particle, (4) auxiliary, (5) modal particle.

Past, present and future tenses are established by a combination of verb stem and auxiliary. Similar means are used to distinguish perfect, progressive, and prospective aspect, of which there are several subtypes in each case.

Clauses

Tibetan clauses are of SOV (subject-object-verb) type, with OSV order also possible. As well as the clause-final verb phrase, the clause may contain a subject, an object, and one or more adjuncts, all noun phrases. Subject and object phrases are regularly omitted without being represented by pronouns if they are not 'new.'

The main clause is the last in the sentence. Nonfinal (subordinate) clauses are usually marked by special particles.

Past-tense and often present-tense clauses are syntactically ergative, the subject of a transitive clause being marked with a particle identical in written form to the 'instrumental' noun particle.

Phonology

Modern central, southern, and eastern dialects have well-developed lexical tone, which has been analyzed in various ways, the simplest being as a two-tone system. In the Lhasa dialect the word is the domain of tone, which is manifested mainly as the pitch (high or low) of its first (or only) syllable. These tonal dialects mostly have few word-initial consonants, with few or no consonant clusters at word-initial position. Plosive and affricate initials always maintain a clear differentiation between an aspirated and an unaspirated series, while voicing has tended to disappear from these series as well as from fricative initials. The dialect of Dingri in southern Tibet has 27 word-initial consonants, all of them simple.

In the western dialects of Balti (spoken in northern Pakistan) and Ladakhi, as well as in some northeastern dialects of Gansu and Qinghai, tone is usually less well developed or absent, with a richer variety of word-initial consonant clusters. The northeastern Amdo Khake (Amdo) dialect has 36 simple word-initial consonants and 78 cluster initials. The writing system, whose spellings are full of consonant clusters, would suggest that the dialect it was based on, perhaps a central dialect of the 7th century, may have been pronounced somewhat like these so-called 'archaic' dialects. However, none of the present dialects approaches the complexity of the spelling system in this respect.

The tonal dialects of central and southern Tibet generally also have a system of vowel harmony. In the Lhasa dialect its domain is a pair of adjacent syllables within a word. Many noun, verb, adjective, and particle constituents vary between an open and a close alternant. Most of the nonparticle constituents in question are spelt with one of the vowels *o*, *e*, or *a*: they will be pronounced with a closer vowel alternant when next to a syllable spelt with *i*, *u*, or the combination *ab*. There is little or no evidence of vowel harmony in the script, suggesting that its development, like that of tone, may have accompanied the progressive loss of consonant distinctions. Whereas the 'archaic' or 'cluster' dialects may typically have nine vowels, corresponding to the five of the script, the 'modern' or 'noncluster' harmonic dialects may have about 25 (in both cases, analyzed nonphonemically).

Honorifics

The written language and most of the dialects have a well-developed honorific system, in which lexical choice of verb is determined by the social status of the person acting as its grammatical subject. There is also a 'respectful' system, in which there is concord between choice of verb and direct or indirect object, and the two systems may be combined. Nouns, adjectives, and verb particles are also affected.

'Well! To believe what you say, the climate of Lhasa seems to be warm in winter and cool in summer!'

Recent History

Developments since World War II have led to the political fragmentation of the Tibetan-speaking world and the increasing influence of other languages, particularly Chinese (Mandarin Chinese), English, Urdu, Hindi, and Nepali. However, the same period has also seen the development of Modern Literary Tibetan (in Tibet and among refugees), Written Dzongkha (in Bhutan), and Written Ladakhi (in Kashmir) as written languages, based respectively on Lhasa Tibetan, spoken Dzongkha, and spoken Ladakhi, but influenced by Classical Tibetan. Some other dialects, including Amdo Khake (Amdo), Kham, and Sikkimese have also had written equivalents devised for them. The late 20th century has also witnessed a Tibetan diaspora, which has led to vastly increased interest in the language and culture, centered on a numerically small but culturally active exile community in India and Nepal. Since the late 20th century, there has also been a marked revival of Tibetan in the Republic of Mongolia. Despite the problems experienced by its speakers, Tibetan remains a living, vigorous, and developing language.

Tigrinya

D Appleyard, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Tigrinya (self-name tɨgrɨŋŋa or tɨgraj), which is spoken in Eritrea and Ethiopia, is the second largest member of the Ethiopian branch of the Semitic family of languages, constituting together with Tigre and the extinct Ge'ez (or Classical Ethiopic) the northern subdivision. Estimates of the number of speakers in both countries vary from 4 to 5 million. Tigrinya is one of the two working languages of Eritrea, where it is the first language of about 50% of the population, and a major national language of Ethiopia. Tigrinya is written in a slightly expanded version of the Ethiopic syllabary, and as a written language has a history only from the latter half of the 19th century, due in great part both to the prestige of Ge'ez as the written language of Christian Ethiopia in the past, as well as to the dominance of its sister language, Amharic, as the language of the Ethiopian court.

Modern Tigrinya shows a considerable degree of dialect variation in the handful of preliminary studies that have been done. The standardization of written Tigrinya took its impetus from the full independence of Eritrea in 1993 and the adoption of Tigrinya as the principal language of the state.

Phonology

Tigrinya has 32 consonant and 7 vowel phonemes. Distinctive are the glottalized consonants and the labialized velars. The velars /k/, /kʷ/, /k'/ and /k'ʷ/ have fricative allophones in postvocalic position including across close juncture between word boundaries: kɐfɐtɐ 'he opened' but jɨxɐffɨt 'he opens', k'orbot 'leather' but ʔɨta x'orbot 'the leather'. As the script has special symbols for these allophones, they will be indicated in the data here. Consonant length is phonemic, except for the glottals and pharyngeals which do not have lengthened counterparts. (See **Table 1** for the consonant chart.)

Ethiopianist convention occasionally employs different symbols from the IPA ones used here; thus, š = ʃ, ž = ʒ, č = tʃ, q = k', ṭ = t', č̣ = tʃ', ǧ = dʒ, ṣ = s', p̱ = p', ñ = ɲ, y = j, k̲ = x, q̲ = x', ḥ = ħ, ' = ʕ, ' = ʔ, ä = ɐ, ə = ɨ. The vowel phonemes of Tigrinya are are /i/, /ɨ/, /u/, /e/, /o/, /ɐ/, and /a/, of which the central vowels /ɐ/, /ɨ/, and /a/ are of particularly frequent occurrence. The mid-central vowel /ɐ/ has a markedly more open allophone in word final position: nɐgɐrɐ = [nɐgɐrɐ̞] 'he spoke', and indeed following a glottal or pharyngeal consonant this is written in the script with the same vowel sign as /e/.

Morphology

Tigrinya, like other Ethiopian Semitic languages, has a complex inflectional morphology, particularly in the verbal system, employing not only prefixes and suffixes but also internal modification of the typical Semitic consonantal root-and-pattern type. Internal modification is also employed in forming many noun plurals from the singular, sometimes in combination

Recent History

Developments since World War II have led to the political fragmentation of the Tibetan-speaking world and the increasing influence of other languages, particularly Chinese (Mandarin Chinese), English, Urdu, Hindi, and Nepali. However, the same period has also seen the development of Modern Literary Tibetan (in Tibet and among refugees), Written Dzongkha (in Bhutan), and Written Ladakhi (in Kashmir) as written languages, based respectively on Lhasa Tibetan, spoken Dzongkha, and spoken Ladakhi, but influenced by Classical Tibetan. Some other dialects, including Amdo Khake (Amdo), Kham, and Sikkimese have also had written equivalents devised for them. The late 20th century has also witnessed a Tibetan diaspora, which has led to vastly increased interest in the language and culture, centered on a numerically small but culturally active exile community in India and Nepal. Since the late 20th century, there has also been a marked revival of Tibetan in the Republic of Mongolia. Despite the problems experienced by its speakers, Tibetan remains a living, vigorous, and developing language.

Tigrinya

D Appleyard, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Tigrinya (self-name tɨgrɨŋŋa or tɨgraj), which is spoken in Eritrea and Ethiopia, is the second largest member of the Ethiopian branch of the Semitic family of languages, constituting together with Tigre and the extinct Ge'ez (or Classical Ethiopic) the northern subdivision. Estimates of the number of speakers in both countries vary from 4 to 5 million. Tigrinya is one of the two working languages of Eritrea, where it is the first language of about 50% of the population, and a major national language of Ethiopia. Tigrinya is written in a slightly expanded version of the Ethiopic syllabary, and as a written language has a history only from the latter half of the 19th century, due in great part both to the prestige of Ge'ez as the written language of Christian Ethiopia in the past, as well as to the dominance of its sister language, Amharic, as the language of the Ethiopian court.

Modern Tigrinya shows a considerable degree of dialect variation in the handful of preliminary studies that have been done. The standardization of written Tigrinya took its impetus from the full independence of Eritrea in 1993 and the adoption of Tigrinya as the principal language of the state.

Phonology

Tigrinya has 32 consonant and 7 vowel phonemes. Distinctive are the glottalized consonants and the labialized velars. The velars /k/, /kʷ/, /k'/ and /k'ʷ/ have fricative allophones in postvocalic position including across close juncture between word boundaries: kɐfɐtɐ 'he opened' but jɨxɐffɨt 'he opens', k'orbot 'leather' but ʔɨta x'orbot 'the leather'. As the script has special symbols for these allophones, they will be indicated in the data here. Consonant length is phonemic, except for the glottals and pharyngeals which do not have lengthened counterparts. (See Table 1 for the consonant chart.)

Ethiopianist convention occasionally employs different symbols from the IPA ones used here; thus, š = ʃ, ž = ʒ, č = tʃ, q = k', ṭ = t', č̣ = tʃ', ǧ = dʒ, ṣ = s', p = p', ñ = ɲ, y = j, k̲ = x, q̲ = x', ḥ = ħ, ' = ʕ, ' = ʔ, ä = ɐ, ə = ɨ. The vowel phonemes of Tigrinya are are /i/, /ɨ/, /u/, /e/, /o/, /ɐ/, and /a/, of which the central vowels /ɐ/, /ɨ/, and /a/ are of particularly frequent occurrence. The mid-central vowel /ɐ/ has a markedly more open allophone in word final position: nɐgɐrɐ = [nɐgɐrɛ̝] 'he spoke', and indeed following a glottal or pharyngeal consonant this is written in the script with the same vowel sign as /e/.

Morphology

Tigrinya, like other Ethiopian Semitic languages, has a complex inflectional morphology, particularly in the verbal system, employing not only prefixes and suffixes but also internal modification of the typical Semitic consonantal root-and-pattern type. Internal modification is also employed in forming many noun plurals from the singular, sometimes in combination

Table 1 The consonant phonemes of Tigrinya

	Bilabial	*Alveolar/dental*	*Palatal*	*Velar*	*Pharyngeal*	*Glottal*
Plosive/affricate	b p	d t	dʒ tʃ	g k		ʔ
Glottalized						
Plosive/affricate/fricative	p'	t'	tʃ'	k'		
			s'	[x']		
Labialized				g^w k^w		
				k'^{w}		
			[x^w][x'^{w}]			
Fricative	f	z s	ʒ ʃ	[x]	ʕ ħ	h
Nasal	m	n	ɲ			
Lateral		l				
		r				
Approximant	w		j			

with the addition of an affix, in 'broken plural' patterns so typical of other Semitic languages such as Arabic: wɐrħi 'month', ʔawarɨħ 'months', kɐnfɐr 'lip', kɐnafɨr 'lips'. Other noun plurals are formed by suffixes alone: sɐb 'man', sɐbat 'men', g^wasa 'shepherd', g^wasot 'shepherds'. Plural formations are determined lexically and cannot be predicted from the shape of the singular form.

In addition to number, nouns also have the category of gender, with two terms linked with male and female in animate nouns, while inanimates generally fluctuate in gender. Gender is mostly observable only in agreement. Definiteness is also indicated in the noun phrase by means of an article, in origin a remote demonstrative: ʔɨtom kahnat 'the priests', ʔɨta waʕro 'the lioness', ʔɨtu s'ɨbbux' wɐddi 'the good boy'. Case relations are expressed by prepositions. Particularly interesting is the use of nɨ-(nɐ- + DEF) as optional marker of a definite direct object, the same clitic also having the function of indicating an indirect object:

nɐ-tu sɨrnaj jɨ-xɨrkɨriʔ-o
OBJ-DEF *wheat* *3(PL)-grind.*IMPERF.PL-*it*
'they grind the wheat'

ʔɨtu k'ɐʃʃi nɐ-ta sɐbɐjti jɨ-ngɐr
DEF *priest* *to*-DEF *woman* *3*MASC.SING-tell.*JUSSIVE*
'let the priest tell [it] to the woman'

Verbs inflect for voice or valency, tense-mood-aspect (TMA), and person. In addition to the base-stem shapes, which are essentially three in number, there are three prefixed stem derivatives for each of these: tɐ-, which essentially has the function of marking passive-reflexive, ʔa- which generally has the function of marking causative-transitive, and a complex formative comprising ʔa-combined with lengthening of the first radical consonant or -t-(i.e., formative ʔat-) before a glottal or pharyngeal. The meanings of derived stems are in addition often lexically defined. There are also specific TMA stem patterns associated with each of these derivational elements: nɐgɐrɐ 'he spoke', tɐ-nɐgrɐ 'it was spoken', bɐxɐjɐ 'he wept', ʔa-bkɐjɐ 'he made someone weep', las'ɐjɐ 'he shaved himself', ʔa-las'ɐjɐ 'he made someone shave himself', fɐnnɐwɐ 'he sent away', ʔaf-fanɐwɐ 'he accompanied someone on his way', etc.

There are four fundamental TMA forms, conventionally referred to as the Perfect, the Imperfect, the Jussive-Imperative, and the Gerundive. The latter is sometimes also described as a Converb. These are marked both by different stem shapes and by different person markers, with the Imperfect and the Jussive having the same set of person markers (the Imperative marks only gender-number). The tense system is considerably augmented beyond these basic forms by means of auxiliaries and periphrastic constructions.

ʔab ʔasmɐra tɐ-wɐlɐd-ku
in *Asmara* PASS-*bear.*PERF-*1*SING.PERF
'I was born in Asmara'

maj ʔ-a-fɨlliħ
water *1*SING.IMPERF-CAUS-*boil.*IMPERF
'I boil the water'

nɐ-tu gɐnzɐb kɨ-[ɨ]-hɨb-ɐkka ʔɨj-jɐ
OBJ-DEF *money* FUT-*[1*SING.IMPF]-*give.*IMPERF-*you* COP-*1*SING
'I will give you the money'

tɨ-ħɨz-o ʔallo-xa
*2*MS.IMPERF-*catch.*IMPERF-*him* *be.*PRES-*2*SING.MASC[PERF]
'you catch him (now)'

ʔab-zu ʕabij gɐza jɨ-x'ɨmmɐt' nɐbɐr-ɐ
in-this *big* *house* *3*MASC.SING.IMPERF-*live.*IMPERF *be.*PAST-3MS.PERF
'he was living in this big house'

s'ɨbaħ tɐmɐlis-ɐ ʔɨ-xɐwwɨn
tomorrow *return.*GER-1SING.GER *1*SING.IMPERF-*be.*IMPERF
'I may come back tomorrow'

The gerundive is used both as a subordinate verb, marking an anterior event in a sequence, and as a main verb form, expressing the result of an action:

mɨs mɐn mɐs'iʔ-ka
*with who come.*GER-2MASC.SING.GER
'with whom have you come?'

nab-tu gɐza tɐmɐlis-a
into-DEF *house return.*GER-3FEM.SING.GER
tɐx'ɐmmit'-a ʔɨngera
*sit.*GER-3FEM.SING.GER *bread*
hab-ɐtt-o
*give.*PERF-3FEM.SING.PERF-*him*
'she returned to the house, sat down, and gave him some bread'

Syntax

Word order in Tigrinya is generally subject-object-verb (SOV), with subordinate clauses preceding the main clause. Noun phrases are also generally head final with modifiers, including relative clauses, preceding the noun.

ʔɨtu ʔanbɐsa zɨ-x'ɐtɐl-ɐ sɐb bɨ-ħ ak'k'i

Tilly, William (1860–1935)

B S Collins, Leiden University, Leiden, The Netherlands
I M Mees, Copenhagen Business School, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

William Tilly, an influential figure in the history of language teaching and practical phonetics, was born in Sydney, Australia, on November 29, 1860, the son of a missionary, Charles Tilley. (Tilly later changed his surname from Tilley so as to correspond to German spelling.)

He had a checkered academic career, first studying Pitman's shorthand (then known as phonography) at a 'Mechanics' Institute' in Melbourne, where he obtained a certificate in 1877. After a period as a theology student at Camden College, he spent just one year at Sydney University and then attended the Public Training School for Teachers. He became a schoolteacher, and in 1885 was appointed director of Dubbo Superior Public School, New South Wales.

However, Tilly had become fascinated by foreign languages. In 1890, he gave up his job to go to Germany, which he considered to be the country that led the world in modern language teaching. He studied a variety of linguistic disciplines, first at Giessen and then at Marburg. In 1893, through the agency of Wilhelm Viëtor, he was appointed to a lectureship in English at Marburg University. He there founded Institut Tilly, a private school dedicated to teaching German and other modern languages by what were regarded at the time as daringly

Tilly, William (1860–1935)

B S Collins, Leiden University, Leiden, The Netherlands
I M Mees, Copenhagen Business School, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

William Tilly, an influential figure in the history of language teaching and practical phonetics, was born in Sydney, Australia, on November 29, 1860, the son of a missionary, Charles Tilley. (Tilly later changed his surname from Tilley so as to correspond to German spelling.)

He had a checkered academic career, first studying Pitman's shorthand (then known as phonography) at a 'Mechanics' Institute' in Melbourne, where he obtained a certificate in 1877. After a period as a theology student at Camden College, he spent just one year at Sydney University and then attended the Public Training School for Teachers. He became a schoolteacher, and in 1885 was appointed director of Dubbo Superior Public School, New South Wales.

However, Tilly had become fascinated by foreign languages. In 1890, he gave up his job to go to Germany, which he considered to be the country that led the world in modern language teaching. He studied a variety of linguistic disciplines, first at Giessen and then at Marburg. In 1893, through the agency of Wilhelm Viëtor, he was appointed to a lectureship in English at Marburg University. He there founded Institut Tilly, a private school dedicated to teaching German and other modern languages by what were regarded at the time as daringly

innovative methods. Tilly subscribed to a radical form of the instructional techniques advocated by the Reform Movement, employing a 'total immersion' approach. He rejected teaching through translation, preferring to expose students to intensive periods of training in the target language; for several weeks on end they were not permitted any opportunity to speak, read, or even hear their mother tongue. Pronunciation was taught through a combination of applied phonetics and strenuous practical articulatory exercises.

Tilly's rigorous approach enjoyed such tremendous success that in 1902 he decided to resign from his university post in order to concentrate on his institute, which he moved to the suburbs of Berlin, first Friedenau and, from 1905 onward, Gross-Lichterfelde. The fame of Institut Tilly and its director spread, with it attracting students from all over the world. Daniel Jones, then an undergraduate reading mathematics at Cambridge, revealed that he was first introduced to phonetics by Tilly in 1900 and thereafter became his lifelong admirer (Collins and Mees, 1999: 12–15).

Tilly continued to teach until 1914, when World War I wrecked his life. After being interned as an alien in Germany for a year, he fled to the United States and for two years was employed in various teaching posts. In 1918 he was appointed Professor of Phonetics at Columbia University, New York, where he soon attracted a body of devoted pupils, many of whom later took up influential academic positions.

Viewed from the present age, Tilly's approach appears curious in that he prescribed a largely British style of pronunciation for his American students; nevertheless he exerted considerable influence on speech training and the teaching of practical phonetics in universities and colleges in the United States. Tilly joined the International Phonetic Association in 1892 and remained a member all his life, being elected to the Council of the IPA in 1900. He is felt to have played a vital role in spreading knowledge of the IPA and its phonetic alphabet not only in Europe but also throughout the United States, especially in the speech departments of American universities.

Tilly produced few publications, and none of real significance. His influence on the development of linguistics appears to have been entirely through the force of his personality and his legendary abilities as a language teacher and practical phonetician. He died in New York in 1935.

Timor Lorosae: Language Situation

J Hajek, University of Melbourne, Melbourne, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Timor Lorosae (or East Timor) achieved full independence on May 22, 2002, after almost 500 years of colonial contact and rule. Under Portuguese control until 1975, it was in turn occupied by Indonesia until 1999. Although only a small nation (est. 998 000 inhabitants), it is notable not only for its difficult political history but also for its linguistic diversity. The estimated number of indigenous languages varies from 15 to 25, and these fall into 2 genetically unrelated groups: Austronesian and so-called Non-Austronesian or Papuan (Trans-New Guinea language family). The best-known East Timorese language is Dili Tetum (or Tetun Dili). It is Austronesian in origin and the principal lingua franca of the nation. It also shows the effects of extensive contact with Portuguese, as can be seen in this following example taken from a local press report (Portuguese loans are in bold):

(1)	iha	**15**	**de**	**Jullu**	loron

aktivu	**politikamente**	sei	atu
active	politically	FUT	IRR
suspende	sira	nia	
suspend	3PL	POS	
funsaun	**governamentál**		
function	governmental		

'on the 15th of July, when the electoral campaign begins, those cabinet members who are politically active will have to suspend their government functions.'

Other Austronesian languages include Mambae, Tokodede, and Galoli. Of the Papuan languages, Fataluku, Makalero, and Makasae form a chain in the extreme east, whereas Bunak is spoken much further to the west. Contact within and between the two language families has been extensive over time, with the result that there are many typological similarities. These include shared lexicon, phonological simplification, the presence of no or very little productive morphology, similar tense–aspect–mood systems, very limited argument marking, if any, on verbs, and the absence of a passive construction. On the other hand, the Austronesian languages remain strongly SVO in terms of sentence structure, whereas the Non-Austronesian languages are characteristically SOV.

Language vitality has in most cases proven to be very robust, regardless of the size of the community. Only one language, Makua (or Lovaia), is immediately threatened: today it has only a handful of speakers, with the rest having shifted to Fataluku.

East Timor's new constitution gives coofficial status to Portuguese and Tetum. Development of the latter is well under way, and a standard form, known as 'Official Tetum,' is now recognized. It is essentially Dili Tetum, with some elements drawn from more conservative, rural varieties of Tetum. Indonesian is still widely spoken, but is being phased out of administration and schools, while Portuguese has now been reintroduced to these same sectors, alongside Tetum.

Tinbergen, Niko (1917–1988)

C J ten Cate, Leiden University Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Niko Tinbergen was one of the founding fathers of the biological study of animal behavior, known as 'ethology,' or currently, as 'behavioral biology.' He received the Nobel Prize in Physiology or Medicine in 1973, together with Konrad Lorenz and Karl von Frisch "for their discoveries concerning organization and elicitation of individual and social behavior patterns." Of the three, Tinbergen is known as the experimentalist. He was a field biologist and keen observer of behavior with the skill to translate observations of animals in their natural habitat into hypotheses about the causation or the adaptive significance of behavior that he tested with simple and elegant experiments.

Tinbergen was born in The Hague The Netherlands. He had one sister and three brothers, one of whom is Jan Tinbergen, recipient of the Nobel Prize in Economics in 1969. Niko was attracted to observing and photographing animals – particularly birds. As an undergraduate student of biology at Leiden University The Netherlands, he often escaped dull lectures to get into the field. In 1930, he began a study focusing on how a solitary wasp, the bee-wolf, used landmarks to find his nest. The 29-page long thesis was finished in a rush (1932) in order to participate in an expedition to Greenland. In 1933, Tinbergen became assistant at the Zoology Department, where he developed a course on animal behavior. He initiated classic laboratory studies on the courtship behavior of sticklebacks, analyzing the interaction of males and females using artificial fish-models. In 1936, Tinbergen met Konrad Lorenz. Their mutual inspiration contributed tremendously to the establishment of ethology as a discipline. Their

It is essentially Dili Tetum, with some elements drawn from more conservative, rural varieties of Tetum. Indonesian is still widely spoken, but is being phased out of administration and schools, while Portuguese has now been reintroduced to these same sectors, alongside Tetum.

Tinbergen, Niko (1917–1988)

C J ten Cate, Leiden University Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Niko Tinbergen was one of the founding fathers of the biological study of animal behavior, known as 'ethology,' or currently, as 'behavioral biology.' He received the Nobel Prize in Physiology or Medicine in 1973, together with Konrad Lorenz and Karl von Frisch "for their discoveries concerning organization and elicitation of individual and social behavior patterns." Of the three, Tinbergen is known as the experimentalist. He was a field biologist and keen observer of behavior with the skill to translate observations of animals in their natural habitat into hypotheses about the causation or the adaptive significance of behavior that he tested with simple and elegant experiments.

Tinbergen was born in The Hague The Netherlands. He had one sister and three brothers, one of whom is Jan Tinbergen, recipient of the Nobel Prize in Economics in 1969. Niko was attracted to observing and photographing animals – particularly birds. As an undergraduate student of biology at Leiden University The Netherlands, he often escaped dull lectures to get into the field. In 1930, he began a study focusing on how a solitary wasp, the bee-wolf, used landmarks to find his nest. The 29-page long thesis was finished in a rush (1932) in order to participate in an expedition to Greenland. In 1933, Tinbergen became assistant at the Zoology Department, where he developed a course on animal behavior. He initiated classic laboratory studies on the courtship behavior of sticklebacks, analyzing the interaction of males and females using artificial fish-models. In 1936, Tinbergen met Konrad Lorenz. Their mutual inspiration contributed tremendously to the establishment of ethology as a discipline. Their

interaction was interrupted during the World War II when they found themselves on opposite sides; Tinbergen was held as a hostage in a prison camp, along with other Dutch intellectuals. In 1947, Tinbergen was appointed Professor in Zoology. His postwar research at Leiden includes another classic: the experimental analysis of the stimuli that made young herring gull chicks peck at the patch on their parents' beaks in order to obtain food. However, the administrative burden at Leiden and his disappointment with Dutch society made him move in 1949 to Oxford, where he was Professor of Animal Behavior from 1966–1974. In 1951, the publication of *The study of instinct*, the first textbook ever written about ethology, brought him fame. He attracted many talented students who would shape the future of the field. While Tinbergen's earlier work focused on the mechanisms underlying behavior, his studies at Oxford shifted toward the adaptive significance and evolution of behavior, such as a study that showed that the egg-shell removal behavior of black-headed gulls reduced the risk of nest predation. Another famous paper addressed the conceptual differences between asking questions about (1) causation (2) development (3) function, and (4) the evolution of behavior. By the time Tinbergen received the Nobel prize his career was beyond its peak and his studies on childhood autism in humans, a joined project with his wife, would never have the impact of his earlier work.

Introduction

Tiwi is an Australian Aboriginal language spoken by the Tiwi people, who number about 2000 and live on Bathurst Island and Melville Island (north of Darwin). Over the decades, since the first extensive contact with Europeans early in the 20th century, the Tiwi culture has undergone considerable change; the Tiwi people have changed from a seminomadic, hunter and gatherer way of life to a more settled lifestyle, and now mainly live in four townships on both islands. The Tiwi people are caught between two cultures, traditional and modern; they desire the benefits of European culture but also want to retain their own identity through some of their traditional ways. Although Tiwi people still do some hunting and gathering and maintain some of their traditional ceremonial life, they are now dependent on a money economy and are mostly Roman Catholic in religion. This change is also reflected in what has happened and is still happening in the language.

The language change is so extensive that young people (even people in their forties) no longer speak or even understand much of the traditional language. Not only does the language of the young people contain a number of English words, but the actual structure of the language has changed. These changes are due to a combination of factors over a period of decades. One of the most significant factors was the setting up of a school for both boys and girls in 1914, with English as the language of instruction and literacy. In addition to this, between 1921 and 1973, most girls were brought up from about the age of six in a dormitory, which effectively cut them off from extensive contact with their families and from hearing the Tiwi language spoken in a regular family context.

The verbal repertoire of the Tiwi people can be characterized by at least five codes: Traditional Tiwi, Modern Tiwi (a modified form of Traditional Tiwi), New Tiwi (an anglicized Tiwi), Tiwi–English, and Standard Australian English. These codes, though

interaction was interrupted during the World War II when they found themselves on opposite sides; Tinbergen was held as a hostage in a prison camp, along with other Dutch intellectuals. In 1947, Tinbergen was appointed Professor in Zoology. His postwar research at Leiden includes another classic: the experimental analysis of the stimuli that made young herring gull chicks peck at the patch on their parents' beaks in order to obtain food. However, the administrative burden at Leiden and his disappointment with Dutch society made him move in 1949 to Oxford, where he was Professor of Animal Behavior from 1966–1974. Introduction

Tiwi is an Australian Aboriginal language spoken by the Tiwi people, who number about 2000 and live on Bathurst Island and Melville Island (north of Darwin). Over the decades, since the first extensive contact with Europeans early in the 20th century, the Tiwi culture has undergone considerable change; the Tiwi people have changed from a seminomadic, hunter and gatherer way of life to a more settled lifestyle, and now mainly live in four townships on both islands. The Tiwi people are caught between two cultures, traditional and modern; they desire the benefits of European culture but also want to retain their own identity through some of their traditional ways. Although Tiwi people still do some hunting and gathering and maintain some of their traditional ceremonial life, they are now dependent on a money economy and are mostly Roman Catholic in religion. This change is also reflected in what has happened and is still happening in the language.

The language change is so extensive that young people (even people in their forties) no longer speak or even understand much of the traditional language. Not only does the language of the young people contain a number of English words, but the actual structure of the language has changed. These changes are due to a combination of factors over a period of decades. One of the most significant factors was the setting up of a school for both boys and girls in 1914, with English as the language of instruction and literacy. In addition to this, between 1921 and 1973, most girls were brought up from about the age of six in a dormitory, which effectively cut them off from extensive contact with their families and from hearing the Tiwi language spoken in a regular family context.

The verbal repertoire of the Tiwi people can be characterized by at least five codes: Traditional Tiwi, Modern Tiwi (a modified form of Traditional Tiwi), New Tiwi (an anglicized Tiwi), Tiwi–English, and Standard Australian English. These codes, though

having characteristics that distinguish them from each other, are not discrete, but rather merge into one another along a spectrum. Each code has within it characteristic styles. For instance, within New Tiwi, there is a difference between the more formal style, used in storytelling on tape and in elicited speech, and the less formal style, used in spontaneous speech. Also, the New Tiwi used by children is different from that used by adults. The Tiwi code used by a person is largely dependent on the age of the speaker, but not exclusively so. Though most young people do not command much Traditional Tiwi (with their understanding being greater than their production), older people do appear to command New Tiwi to some extent and usually use it in speaking with younger people. In addition to the diversity of codes, the situation is made more complex by switching between codes, including English.

Traditional Tiwi

In Traditional Tiwi (TT), there are four vowels: a, i, o, u. The consonants are given Table 1, in which the symbols used are the orthographic ones developed when Tiwi became a written language 30 years ago. The prenasalized and labialized stops are interpreted as single consonants on the basis that there are no unambiguous double consonants in Tiwi. The Tiwi syllable pattern is consonant-vowel (CV) or V with no closed syllables.

Tiwi nouns are divided into two classes, masculine and feminine. For humans (and some animals), the distinction is on the basis of natural sex. For non-humans, the distinction is made on other criteria, normally semantic grounds. Plurality is marked only on human nouns, and the distinction between masculine (MASC) and feminine (FEM) is lost in plural (PL) nouns. Adjectives agree with the nouns that they qualify in gender and plurality (when applicable), as shown in the following examples:

(1) arikula-ni tini
big-MASC man
'big men'
arikula-nga tinga
big-FEM woman
'big women'
arikula-pi tiwi
big-PL people
'big people'

Traditional Tiwi is a polysynthetic language, with the inflected verb having an extremely complex structure. It is one of the prefixing languages of northwestern Australia but it has not been found to be directly related to any of them. The verb is able to take a number of affixes (mainly prefixes), indicating subject person, direct or indirect object person, tense, aspect, mood, time of day, and distance in time or space, for example. The nucleus of the verb contains a verb root but may also contain one or more incorporated forms that add some other nominal, stative, or verbal meaning (abbreviations: CONT, continuous; INCL, inclusive; SUBJUNC, subjunctive; EMPH, emphatic; CON, connective; CAUS, causative):

(2) Pi-rri-mini-wujingi-pirni.
they-PAST-me-CONT-hit
'They were hitting me.'

(3) Yinkiti nga-ma-wun-ta-y-akirayi.
food we(INCL)-SUBJUNC-them-EMPH-CON-give
'We should give them food.'

(4) Nganti-ri-ma-rri-pi-y-ajirringi-kitikim-ani warta.
we.PAST.FEM-CON-with-CON-bush
long.thing-CON-crocodile-drag-PAST.HABIT
'We used to drag the crocodile to the bush with the spear still in her.'

(5) Taringini yi-mini-maji-wutu-wirri.
snake he.PAST-me-on-horse-bite.
'A snake bit me while I was on a horse.'

In Traditional Tiwi, there is also a verb phrase, consisting of a free-form verb, which carries the basic

Table 1 Traditional Tiwi consonants

Feature	*Apical*		*Laminal*	*Peripheral*	
	Alveolar	*Postalveolar*	*Dental/Palatal*	*Dorsal*	*Labial*
Stops	t	rt	j	k	p

[a]The symbol 'g' represents a velar fricative, which seems to behave like a semivowel.

meaning, and an auxiliary verb, which can carry the same inflections as an independent verb. The class of free-form verbs occurring in this type of construction is small and, even in TT, may be expanded by the use of English loan verbs.

(6) Papi awungarra pi-ri-maji-wutuwu-mi.
arrive here they.PAST-CON-on-horse-do
'They arrived here on horses.'

(7) mwarliki nga-ma-wun-ta-m-amigi
bathe we(INCL)-SUBJUNC-them-EMPH-do-CAUS
'we should cause them to bathe'

New Tiwi

The speech of young people incorporates a number of changes to the traditional language, including phonological changes and changes in vocabulary, in noun classification, and in syntax, such as word order. However, the greatest change is in the verbs. New Tiwi (NT) is no longer a polysynthetic language but has become more isolating. Most of the verbal inflection has been lost, with simple verb forms mostly replacing the complex inflected verbs. The NT verb form is based on the TT verb phrase. However, the small class of free-form verbs has been expanded by a greater use of loan verbs from English and, in a few cases, by the use of the singular imperative as a free-form verb. The auxiliary verb may or may not be used, depending on the formality of the occasion. When it is used, there are very few inflections retained, usually only those prefixes marking subject and tense, though even these are often changed in form. The following three examples are comparisons of New Tiwi and Traditional Tiwi:

(8a) NT: Wokapat yi-mi.
walk he.PAST-do
'He walked.'
(8b) TT: Yi-p-angurlimayi.
he.PAST-CON-walk
'He walked.'

(9a) NT: Lukim ngi-ri-mi nginja.
see I-CON-do you.SING
'I saw you.'
(9b) TT: Ngi-rri-min-j-akurluwunyi (nginja).
I-PAST-you(SING)-CON-see (you.SING)
'I saw you.'

(10a) NT: Tamu ji-mi.
sit she.PAST-do
'She sat.'
(10b) TT: Ji-yi-muwu.
she.PAST-CON-sit
'She sat.'

Note: *tamuwu* is the singular imperative form in Traditional Tiwi.

Young people sometimes use the continuous action prefix *wuji-*, but other aspects and moods are given by loanwords from English, such as *stat* 'start,' *tra* 'try,' *jut* or *shut* 'should,' and *ken* 'can.'

(11a) NT: Yoyi a-wuji-ki-mi.
dance he-CONT-CON-do
'He is dancing.'
(11b) TT: Yoyi a-wuji-ngi-mi.
dance he.NONPAST-CONT-CON-do
'He is dancing.'

(12) NT: Jirra tra kirrim ji-mi warra.
she try get she.PAST-do water
'She tried to get some water.'

Since the verbs in NT no longer have the inflections of TT, there is a greater use of nouns and pronouns, to indicate the participants, and dependence on time words or the context, to indicate the tense. In NT, there is also considerable use of other English loanwords. In the speech of young people, particularly children, these may include words such as *pijipiji* for 'fish,' for which there is a traditional Tiwi equivalent. In general, NT can be said to be an 'amalgam' of Tiwi and English – in other words, a 'mixed code,' like a pidgin (or creole) Tiwi. This type of amalgam distinguishes 'mixing' from 'switching' between codes, though it is often hard to tell where mixing ends and switching begins. The following example from a 4-year-old boy shows the mixing in his Tiwi and the switching between his New Tiwi and his Tiwi–English (TE) in the same utterance:

(13) Ya kilim ja. [NT] I kill you, mate. (TE)
I hit you (SING) I hit you mate
'I'll hit you, mate.'

Modern Tiwi

What is normally thought of as Modern Tiwi (MT) is a style, or a range of styles, between Traditional Tiwi and New Tiwi; in general, ModernTiwi is a modified or simplified style of TT. In Modern Tiwi, people use more verbs with TT verb roots than are used in NT, but the verbs do not have the same richness of inflection as in TT. In general, the only affixes retained in the verb are the subject and tense prefixes and others that are not able to be expressed externally in TT, such as some aspect and mood affixes. Other affixes and incorporated forms are normally omitted, particularly those affixes indicating whether an action was done in the morning or evening and the object prefixes. These are either expressed by free-form words or are understood from the context.

(14a) MT: Japinari yi-pirni ngiya.
morning he.PAST-hit me
'He hit me in the morning.'

(14b) TT: (Japinari) yu-watu-mini-pirni.
morning he.PAST-morning-me-hit
'He hit me in the morning.'

Another feature of MT is the loss of distinction between first-person plural inclusive and exclusive subjects, as is also the case in NT.

(15a) TT: Ngimpi-ri-majirripi.
we(EXCL)NONPAST-CON-lie.down
'We (but not you) lie down.'
Nga-ri-majirripi.
we(INCL)-CON-lie.down
'We (including you) lie down.'

(15b) MT: Nga-ri-majirripi.
we.NONPAST-CON-lie.down
'We lie down.'

Conclusion

The present-day language situation among the Tiwi people is very complex; a broad overview cannot begin to describe the differences that there may be among the four townships on Bathurst and Melville islands. Briefly, there are certain domains wherein a particular code is appropriate and may be used exclusively (or almost exclusively). In other situations, more than one code may be used, depending on the speakers and hearers and the formality of the occasion. Traditional Tiwi is used in the traditional ceremonies and songs, in some liturgy in the church, and in some written material. In situations in which non-Tiwi people are involved, such as administrative and work situations, English is mostly used, though the English used by the Tiwis may vary between Standard English and Tiwi–English. English is also used in the homily and in some of the liturgy and songs in church, and in all of the schools, at least in formal education. Modern Tiwi is used in bilingual education in the primary school on Bathurst Island and in some formal situations, when young Tiwi people are involved, such as when giving a formal speech in Tiwi. There is some written material in Modern Tiwi, produced by the schools and by the author (Jennifer Lee) and her Summer Institute of Linguistics colleague, Marie Godfrey (New Tiwi is not generally acceptable in written form). New Tiwi is the common code of young people, though with considerable code switching with English in most situations, depending on the speakers and hearers.

Tobler, Adolf (1835–1910)

N Lioce, IVO Sint-Andreis, Belgium
P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born May 23, 1835 in Hirzel (Switzerland), Adolf Tobler studied classical and modern philology in Zurich and Bonn (attending Diez's lectures in 1856–1857). After receiving his Ph.D. at the University of Zurich in 1857, and his Habilitation in Bern in 1867, he became the first professor of Romance philology at the University of Berlin, where he remained until his death on March 18, 1910.

Tobler's research was focused on Gallo–Romance, and to a much lesser extent Italian, philology. His approach was rooted in the careful study and criticism of medieval literary texts, of which he tried to understand the finest details of the vocabulary and the syntax. Tobler stressed the need to place the texts in the cultural and historical setting of their times in order to understand their contents.

Tobler's main linguistic achievements were his extensive dictionary of Old French, published posthumously by his student Erhard Lommatzsch (1886–1975) and, after the latter's death, by a team of Romance scholars, and his fine-grained, very detailed studies of morphosyntactic phenomena in Old French, also sporadically in Modern French. His scattered grammatical analyses, some 100 in total, were gathered in five volumes (Tobler, 1886–1912) from which a solid syntactic theory can be distilled (see de Boer, 1946–1947). These *Vermischte Beiträge*, though primarily concerned with problems of diachronic syntax, had a major impact on the grammaticography of Modern French at the beginning of the 20th century. Tobler's morphosyntactic analyses were closely linked with his lexicographical work on Old French; in fact, he did not draw a boundary between lexical and grammatical phenomena. The lexicographical description of Old French is primarily based on medieval literary texts, and much less so on administrative and scientific texts; in spite of this limitation, the *Altfranzösisches Wörterbuch* (Tobler and Lommatzsch, 1915–) remains an indispensable tool for students of Old French and of the history of the French lexicon, because of its sound philological foundations and its accurate references to textual occurrences.

Tobler also wrote a classic textbook on French versification (1880; later translated into French). Adopting a historical–evolutionist approach, Tobler showed Modern French prosody to be based on medieval metrics.

In his linguistic, literary, and philological writings, Tobler was guided by historicist principles; in the explanation of facts he often appealed to logical and psychological factors. Tobler accorded scientific value only to historical approaches of linguistic and literary phenomena. A typical representative of philological text study, he strongly opposed modernist reforms in foreign language teaching and remained strongly attached to the traditional conception of Romance philology.

Tocharian

R Kim, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Tocharian (Tokharian) is the conventional name for two related, extinct Indo–European (IE) languages known from documents found in the oases north of the Taklamakan desert in Xinjiang (Chinese Turkestan). The languages are now generally referred to as Tocharian A (TA) and Tocharian B (TB); the alternatives *Osttocharisch* and *Westtocharisch* (East and West Tocharian) are still used by German scholars; 'Turfanian' and 'Kuchean' are obsolete terms.

Tocharian is known from manuscripts discovered by archaeological missions to Xinjiang in the years preceding World War I, in particular those led by Sir Aurel Stein of the United Kingdom, Albert von le Coq of Germany, and Paul Pelliot of France. In addition to a wealth of Middle Iranian documents, the expeditions brought back others in unknown languages, written in the 'slanting' Brāhmī script of Central Asia. In 1908 the German philologists Emil Sieg and Wilhelm Siegling conclusively identified them as non-Indo–Iranian IE languages, which they labeled 'Indo–Scythian'; they also succeeded in distinguishing TA and TB.

The manuscripts are dated to approximately the sixth to eighth centuries AD, but further chronological precision is difficult. The TA records were discovered in and around Turfan and Qarašahr and are entirely of Buddhist religious content; most are translations or adaptations of Sanskrit originals. TB documents were found across the northern Silk Road from Kuča in the west to Turfan in the east; most are Buddhist in content, but a solitary love poem and a large number of monastery records, as well as caravan passes and cave graffiti, indicate that TB was the vernacular of at least part of the population in these areas in the later first millennium.

TA is remarkably uniform linguistically, and a number of facts indicate that it was no longer spoken at the time of the surviving manuscripts, but served as a sort of liturgical language among speakers of TB and Old Turkic. The TB documents exhibit considerable variation on all levels. On the basis of certain phonological and morphological features, they have been divided into western, central, and eastern dialects, but as vernacular TB sources (e.g., caravan passes or cave graffiti) mostly show 'eastern' characteristics, this division may also reflect chronological and/or sociolinguistic differences. Another source of variation is poetic: many forms in TB verse passages have been adjusted by one syllable to fit the meter; also characteristic is *pudñäkte* 'Buddha' for prose *pañäkte*.

The speakers of Tocharian played an important role in the Buddhist civilization of pre-Islamic eastern Central Asia, but their exact identity remains unknown. The name 'Tocharian' rests mainly on the form *twγry* in an Old Uyghur colophon, but both the reading and the identification have been challenged. It seems certain that the speakers of TA and TB were not the 'Tocharians' of antiquity (Strabon's Τόχαροι; Skt. *Tukhāra-*). Among the figures in the spectacular Buddhist cave paintings of the region are some with red hair and green or blue eyes, and many have speculated that these were the Tocharians; more recently, the discovery of red-haired, 'Western'-looking mummies in the Taklamakan made headlines in the mid-1990s, but once again we cannot be sure which language they spoke. In any case, the speakers of Tocharian (more precisely, TB; see above) began to shift to Turkic in the later first millennium AD; the language was probably extinct by 1000.

Although they differ in numerous respects and certainly were not mutually intelligible, TA and TB were structurally similar, characterized by right-headed constituent phrases, a system of agglutinating nominal case suffixes, and the central role of aspect and tense in verbal morphology. The two had doubtless been diverging for several centuries before the time of our documents, so that their latest reconstructible common ancestor, Proto-Tocharian (PT), must be dated to the last centuries BC.

The variety of Brāhmī script used to write Tocharian lacked symbols for distinctively Tocharian sounds such as labiovelar [k^w] and (in TB) the diphthongs [ew], [ow], [aw], [ay], and contained signs (*akṣara*s) for Sanskrit and Prakrit phonemes absent in the language (e.g., *v, h*, and the voiced, aspirated, and retroflex obstruents; the latter are used almost exclusively in Indo–Aryan borrowings). The most remarkable innovation of the Tocharian writing system is the creation of a series of *Fremdzeichen* ('foreign signs') to represent sequences of consonant + the vowel *ä*, probably a high central [ɨ]; these exist for most, but not all consonants, and are used apparently interchangeably with the normal *akṣara* plus two subscript dots (hence the transcriptions *tä*, *ñä*, etc.). A second vowel (usually *u*) can be combined with a ligature (e.g., *kse* + *u*, transcribed $k_u se$); such 'subscript' *u*'s may denote either a labiovelar or a reduced/syncopated vowel.

Recent research has elucidated most of the principal phonological developments from Proto-Indo–European (PIE) to PT and the two Tocharian languages. The PIE series of voiceless, voiced, and voiced aspirate

stops have famously merged, except that *t, *d^h > PT *t remained distinct from *d > PT *t^s. PIE palatals and velars merged in PT, but labiovelars and sequences of palatal/velar + *w remained distinct. Palatalization before front vowels created new allophones that then became phonemic and gave rise to a number of morphologically conditioned alternations. The vowels underwent many changes, including loss of contrastive length. TB is in general the more phonologically conservative of the two languages, especially the western dialect; in contrast, TA has undergone sweeping changes, principally involving the vowel system.

The noun distinguishes two genders, masculine and feminine, plus a class of nouns of 'alternating' gender that take masculine agreement in the singular and feminine in the plural. Nouns and adjectives contrast for singular, plural, and dual. Nouns inflect for nine cases in each language, but only the three 'primary' cases, nominative, oblique, and genitive, are of PIE date; the remaining 'secondary' case suffixes are agglutinative, added to the oblique of singular and plural alike, and attached only to the last element of a noun phrase (e.g., TA *kuklas yukas oṅkälmās-yo* 'with chariots, horses, and elephants'). Although their functions mostly coincide, few of the suffixes are clearly cognate: cf. comitative TB *-mpa*, TA *-aśśäl*, ablative TB *-meṃ*, TA *-äṣ*. Most nonfeminine nouns have identical forms for nom. and obl. singular, derived from the PIE accusative, but masculine nouns denoting rational beings have secondarily created a distinct oblique in TB *-ṃ*, TA *-(a)ṃ*.

The numerals are of clear IE provenance: TB *wi*, TA m. *wu*, f. *we* '2,' TB m. *trey* ~ *trai*, f. *tarya*, TA m. *tre*, f. *tri* '3,' TB m. *śtwer*, f. *śtwāra*, TA *śtwar* '4,' TB *piś*, TA *päñ* '5,' TB *ṣkas*, TA *ṣäk* '6,' TB *ṣukt*, TA *ṣpät* '7,' TB *okt*, TA *okät* '8,' TB, TA *ñu* '9,' TB *śak*, TA *śäk* '10,' TB *ikäṃ*, TA *wiki* '20.' The prehistory of the personal and demonstrative pronouns contains a number of unsolved problems; noteworthy is the existence of separate masculine and feminine forms for 'I' in TA, m. *näṣ*, f. *ñuk* (vs. TB m./f. *ñäś*, *ñiś*).

The verb exhibits numerous idiosyncratic developments alongside a wealth of interesting and archaic features and has played an increasingly prominent role in the ongoing debate over the reconstruction of the PIE verbal system. The inherited voice distinction of active and mediopassive is robustly preserved. An interesting, if often overemphasized, feature is the widespread suffixation of PT *-skë- ~ *-ṣṣə- (> TB /-ske-/ ~ /-ṣṣə-/ ~ /-s-/; TA *-sa-* ~ *-ṣ-*) to derive transitives to intransitive roots and causatives to many, but not all, transitive roots. Both languages have the same morphological categories of present and imperfect (= nonpast and past of the imperfective stem), subjunctive/future and optative (= nonpast and past of the perfective stem), imperative, and preterite; nonfinite forms include the infinitive, gerundives I and II (denoting respectively obligation and possibility), a verbal noun or 'abstract,' almost always built to gerundive II; and a present and preterite participle. Most inflectional categories and patterns of verbal stem derivation are of PIE date, including reflexes of nasal and stative presents and root and (pre-)sigmatic aorists. Approximately a dozen verbs are suppletive, second only to Old Irish among IE languages. Among numerous unsolved problems are the remarkable paucity of simple thematic presents, and the origin of the Tocharian subjunctive and its relation to the classical PIE subjunctive and perfect.

Nominal compounds are fairly common, as are complex derivatives like TB *raddhi-lak-ä-ṣ(ṣ-äly)-ñeṣṣe* 'of causing to see wonders.' As the Tocharian languages are left-branching, the verb is usually clause-final in prose documents but may be raised for various pragmatic effects; verse texts not surprisingly offer much variation.

Early on, many Indo–Europeanists were struck by the apparent connections between Tocharian and the western IE languages, particularly Celtic and Germanic. Today, however, the emerging consensus holds that Tocharian is not closely related to any other branch of IE but, rather, was the second after Anatolian to diverge from the ancestral speech community.

Little is known of the earliest contacts between Tocharian and other languages. Several strata of Iranian loanwords may be distinguished: the oldest appear to date from the Old Iranian period, followed by a small set whose preforms strongly resemble Ossetic; most recent are loans from neighboring Eastern Middle Iranian languages, particularly Khotanese. A few old Indo–Aryan borrowings go back to the pre-PT period – note TB (prose) *pañäkte*, TA *ptāñkät* 'Buddha' and TA *pñi* 'puṇya', reflecting the change of *u > PT *ə – but the huge number of loanwords from Sanskrit and Prakrit entered the language comparatively recently; some have been (partly) assimilated to Tocharian phonology, but many retain their original orthography and may have belonged only to high religious registers. Certain old loanwords in Chinese appear to come from Tocharian, for example, MidChin. *mjit (or sim.) 'honey' ← PT *m^yətə (cf. TB *mit*). In light of the Tocharians' ultimate linguistic shift to Turkic, it is interesting to note that a few important Turkic words may be of Tocharian origin: cf. TB *okso* 'ox', *kauṃ* (*kom*) 'day, sun' → Proto-Turkic *öküz, *kün.

Toda

P Bhaskararao, Tokyo University of Foreign Languages, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Toda is the name of an ethnic group that resides on the Nilagiri mountains (=Nilgiris) in South India (with its major town of Udagamandalam = Ooty = Ootacamund located at 11.24°N and 76.44°E). The lofty Nilagiri mountains (with peaks rising above 2400 m) are the home of five culturally interrelated ethnic communities – Toda, Kota, Kurumba, Irula, and Badaga – all speaking different Dravidian languages. The Todas recognize the mutual relationship and the historical interdependency among these five communities. Though they are known as Todas to outsiders, they call themselves oˑŁ (meaning 'Toda person'), and their language, oˑŁ-poˑš (poˑš 'language'). The Toda language contains different words for each of the five Nilagiri communities. They are oˑŁ (Toda = tōḍa), *kwïˑf* (Kōṭa), *kurb* (Kurumba), *erl* (Iruḷa), and *maˑf* (Baḍaga). Though the Toda language does not have a word or a phrase to denote all these five communities together as one group, it has the word, *pöˑṛ*, which means 'a nonwhite low lander (who does not belong to any of the five Nilagiri communities.)'

Toda

P Bhaskararao, Tokyo University of Foreign Languages, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Toda is the name of an ethnic group that resides on the Nilagiri mountains (=Nilgiris) in South India (with its major town of Udagamandalam=Ooty=Ootacamund located at 11.24°N and 76.44°E). The lofty Nilagiri mountains (with peaks rising above 2400 m) are the home of five culturally interrelated ethnic communities – Toda, Kota, Kurumba, Irula, and Badaga – all speaking different Dravidian languages. The Todas recognize the mutual relationship and the historical interdependency among these five communities. Though they are known as Todas to outsiders, they call themselves oˑŁ (meaning 'Toda person'), and their language, oˑŁ-poˑš (poˑš 'language'). The Toda language contains different words for each of the five Nilagiri communities. They are oˑŁ (Toda=tōḍa), *kwïˑf* (Kōṭa), *kurb* (Kurumba), *erl* (Iruḷa), and *maˑf* (Baḍaga). Though the Toda language does not have a word or a phrase to denote all these five communities together as one group, it has the word, *pöˑṛ*, which means 'a nonwhite low lander (who does not belong to any of the five Nilagiri communities.)'

This term demarcates all the five communities together as a group from the rest of the people of India. A white person (who is expected not to be an Indian) is called *ars*.

Toda language is endangered, with just around 900 speakers, most of whom are bilingual in their mother tongue and in Tamil language, the most dominant language in the area. There is twofold division among the Todas, conventionally called 'moieties' in anthropology. The moieties are *to·r̄θaŝ* and *töwfiŁy*. Except for a few words and phrases, no significant dialectal differences are found between these two moieties.

Phonology

Among the languages of India, Toda possesses a unique and complex inventory of phonemes. It is the sound system of this language that makes it sound 'very foreign' to many non-Todas, making them to imagine wildly that it is because the Todas were originally some exotic people such as Greeks, Persians, and so forth their language contains so many 'foreign' sounds. All of these 'exotic' sounds are derivable historically from a proto-stage through an intricate set of rules.

In addition to the typical five vowels (and their long counterparts) available in most of the Dravidian languages, the Toda vowel inventory contains front rounded vowels, /*ü*, *ö*/, and a back unrounded vowel, /*ï*/. In addition, each of the eight vowel positions has a short and long counterpart. This results in a total of 16 contrasting vowel phonemes viz., *i*, *i·*, *e*, *e·*, *ü*, *ü·*, *ö*, *ö·*, *ï*, *ï·*, *u*, *u·*, *o*, *o·*, *a*, *a·*. The inventory of consonants presents the most complex system known for any Indian language, and some of the consonantal contrasts found in this language are not encountered in any other language in the world. There are four voiceless sibilants contrasting at dental, alveolar, palatal, and retroflex places: /s, ŝ, š, ṣ/. There are three non-sibilant fricatives: /f, θ, x/. By some morphophonemic changes, the voiced counterparts of these fricatives also attain contrastive status. Voiceless and voiced plosives contrast at seven places of articulation. They are labial (p, b), dental (t, d), denti-alveolar (c, ẓ), alveolar (t̲, d̲), palato-alveolar (č, j), retroflex (ṭ, ḍ), and velar (k, g). There are three nasals: /m, n, ṇ/. This is the only known language that has a set of three contrastive trills and four contrastive laterals. The trills are dental /r/, alveolar /r̲/, and retroflex /ṛ/, and the laterals are voiceless alveolar /ɬ/, voiced alveolar /l/, voiceless retroflex /Ł/ and voiced retroflex /ḷ/ (Tables 1 and 2).

Table 1 Vowels

	FU		*FR*		*CR*	*CU*		*BU*		*BR*	
High	i	i·	ü	ü·				ï	ï·	u	u·
Mid	e	e·	ö	ö·						o	o·
Low						a	a·				

Sentences

Toda is an SOV language with syntax very similar to that of other Dravidian languages. The so-called 'extra-subject predication' (Emeneau, 1984: 51) is peculiar to this language; for example,

o·n kïfy köṭ-s-pini
I$_{NOM}$ ear$_{NOM}$ got.destroyed-PAST.SUFFIX-1ST PERSON.SINGULAR
'My ears were ruined'

In a parallel sentence in other Dravidian languages, a dative-subject and the verb in concord with the object are expected.

The reportative/quotative sentences are also different in this language. The subject of the embedded sentence is marked for accusative case; for example,

en-n "pod-či"ïd̲, ka·k öštši/uncsi
I-ACC "will.come.3p" QUOT, crow said.3PERSON/ thought.3PERSON
'The crow said/thought that I would come'

Pronouns and Nouns First- and second-person pronouns are differentiated for number and inclusiveness (inclusion or exclusion of the addressee). There is no differentiation on the basis of sex among the pronouns. The pronouns are: first person singular: *o·n*, exclusive plural *em*, inclusive plural, *om*; second-person singular *ni·*, plural *nïm*; third person *aθ* (and its

Table 2 Consonants

Fricatives	f	(v)	θ	(δ)	s	(z)	ŝ	(ẑ)	š	(ž)	ṣ	(ẕ)	x	(γ)
Trills				r				r̲				ṛ		
Approximants										y				w
Laterals							ɬ	l			Ł	ḷ		

plural *aθ-aˑm* containing the plural suffix *-aˑm*). Nouns are either simple or derived. Simple nouns are mono-morphemic, and derived nouns contain a suffix; for example, *kurb* 'Kurumba community,' *kurbč* 'a Kurumba female.'

Nouns are inflected for plurality and case by means of suffixes. *-aˑm* is the most common plural suffix (*ïr* 'buffalo,' *ïr-aˑm* 'buffalos'). Some of the case suffixes are accusative *-n*, dative *-k*∼*-g*, locative -ŝ, ablative *-ŝn*, instrumental *-ïṭ*, causal *-ïd*, sociative *-wïṛ*. Some of the postpositions are *pok* 'at the time of,' *taŝ* 'above.' Some case forms are also formed by adding post-positions.

Numerals and Modifiers

Formation of numerals follows the general Dravidian pattern. Numerals 1000, 100, and 1–10 are monomorphemic. They are *wïḏ* '1,' *eˑḍ* '2,' *muˑḏ* '3,' *noˑng* '4,' *üẓ* '5,' *oˑṛ* '6,' *öw* '7,' *öṭ* '8,' *wïnboθ* '9,' *pot* '10,' *noˑṛ* '100,' and *soˑfer* '1000'. The formula for forming decades is 2, 3, and so on, followed by 10 (e.g., *mu-poθ* [3–10] '30'). The formula for series between decades (e.g., 31–39) is the numeral for decade followed by 1–9 (e.g., *mu-poθ-eˑḍ* [3-10-2] 'thirty-two'). Ordinals are derived from the above cardinals by the addition of the suffix *-oˑθ* (e.g., *eˑḍ-ö̱θ* 'second').

As in the case of several other Dravidian languages, it is difficult to demarcate adjectives from nouns. A few descriptive adjectives are *kïṛ/kin* 'small,' *per* 'big,' *poč* 'green.' Similarly, adverbs as a class consists of a very few members. Most of the forms that function as adverbs are inflected nouns or forms derived from verbs. A few clear cases of adverbs are *maxaṛ* 'earliest,' *pïn* 'later, afterwards.'

Oblique Forms

Some nouns, numerals, and so on are converted into oblique forms when some case suffixes are added to them. The most common oblique suffix is *-t*; for example, *meˑṇ* 'tree': *meˑn-t-k* 'to the tree' [*-k* is the dative suffix]; *eˑḍ* 'two': *nïm eˑŁ-k* 'to you both.'

Verbs

The structure of Toda verb is quite complex compared to the rest of Dravidian languages. A verb is either simple (containing only a verbal root) or derived (root+derivative suffix). The most common derivate suffix is a transitive/causative suffix (e.g., *nïl-* 'to stand,' *nïl-c-* 'make to stand'). In a majority of cases, the transitive/causative suffix fuses with the ending of the root, as in *oˑṛ-* 'to become dry,' *oˑṭ-* 'to dry something.' Mediative forms can be derived from a simple or derived base by addition of the suffix *-eṭ*∼*eṭy-*. The mediative form denotes a type of indirect or noncontactual causation; for example, *miy-*∼*mis-* 'to graze (intr),' *miˑc-* ∼ *miˑč-* 'to graze (tr)' occurring in: *ïr-aˑ-n a tïṭ-ȧṛ miˑc* '(Go and) graze (tr.) the buffalos over that hill!'; *mors-fy ïr-k wïḷḷy mad kwïṛt miy-eˑṭ* 'Give some good medicine to the buffalos with foot-and-mouth disease and make them graze!'

Almost all of the Toda verbal bases have two morphophonemic alternants, conventionally called Stem 1 (S1) and Stem 2 (S2). S2 enters into a majority of inflections. Historically it corresponds to the past-tense stem in some of the South Dravidian languages (such as Tamil). S1 is the etymologically underlying form, and the corresponding S2 is derivable by a set of rules from it. For instance, 'to stand' -S1: *nïl-*> S2: *nïḏ-*. In addition, there is a third variety of stem called the 'Desiderative' stem that is peculiar to Toda among the Dravidian languages. The desiderative stem takes some inflectional suffixes.

A verb base alone functions as the singular imperative form; for example, *part* 'You(sg.) pray!.' All other full verbal forms contain a verb base followed by an optional inflection layer for tense/mode. A further optional inflectional layer of Pronominal suffixes (PN) that reflects the pronominal class of the subject terminates the verb. The third-person PN suffix is selected if the subject is any noun (singular or plural) or if it is a third-person pronoun (singular or plural). When the subject is a personal pronoun, the corresponding PN suffix is chosen. The PN layer is very complex in Toda compared with other Dravidian languages. It contains several sets of PN suffixes that are added to different inflections. In the case of some inflections such as Non-Past, just the verb base followed by the appropriate PN suffix without an intervening tense suffix functions as the full verb. Another complexity of the PN suffix layer is the occurrence of two morphophonemic alternants of the same suffix across two sets that are conventionally called Paradigm I and Paradigm II. Paradigm I occurs before a terminating declarative suffix *-i*, and Paradigm II elsewhere.

Examples of a few tenses/modes are listed here (the verb base *tïn-* ∼ *tïḏ-* 'to eat' is followed by one or more of the following suffixes: T = tense/mode suffix, Pn = Person suffix, D = declarative suffix: Past: *tïḏ-s-s-i* [T-Pn-D] 'He/she/it/they ate'; Non-past: *tïḏ-č-i* [Pn-D] 'He/she/it/they will eat'; Negative: *tïn-ïn-i* [Pn-D] 'I did/do/will not eat'; Voluntative: *tïn-g-y* [T-Pn] 'You(sg) may eat'; Tenseless: *tïḏ-en* [T-Pn] 'I eat'; Plural Imperative: *tïn-ŝ* [Pn] 'You (pl.) eat!'; Conditional : *tïḏ-u-fiṛ* [Pn-M] 'If he/she/it eats'; Contemporaneity : *tïḏ-u-k* [Pn-M] 'while we (incl) were eating'; *tïḏ-pok* [T-Pn] 'when (somebody) ate'; Purposive: *tiḏ-pïk* [T-P] 'for the sake of eating.'

A number of verb bases also function as auxiliary verbs (Ax) in producing various modal forms. Some examples are: *kuty-ïs-s-pini* [*kuty*-'to embroider'-Ax-T-Pn] 'I knew how to embroider'; *pod-kïš-ïyi* [*pod*-'to come'-Ax-Pn] 'He could not come'; *noby-pïṭ-s-pini* [*noby*-'to believe'-Ax-T-Pn] 'I believed (him) wrongly,' *tïḏ-kuṛy-s-py* [*tïḏ*-'to eat'-Ax-T-Pn] 'You(sg) have completed eating'; *aˑfoṭ-kwïḏ-ïṭi* [*aˑfoṭ*-'to talk'-Ax -Pn] 'Don't talk to yourself,' *kïs-s-pod-s-si* [*kïs*-'to do' -Ax-T-Pn] 'He went on doing,' *köṭ-s-piˑ-č-či* [*köṭ* 'to be spoiled' -T-Ax-Pn] 'It will get spoiled.'

A set of suffixes derives verbal forms that are used as modifiers; for example, *tïḏ-fy oˑŁ* 'man who ate'; *tïḏ-θ oˑŁ* 'man who ate (more definite)'; *tïḏ-t oˑŁ* 'man who eats'; *tïḏ-p oˑŁ* 'man who can eat'; *tïn-oˑ-fy oˑŁ* 'man did/does not eat.' The suffix *-t* also derives a verbal noun as in: *nöw kïs-t* 'making a song' [*kïy-* ~*kïs-* 'to make, do'].

Vocabulary

Before the Todas came into contact with words from the languages from the plains such as Tamil, Hindi, and English, their borrowed vocabulary must have consisted of a few words from the language of their neighbors such as Badagas. In contemporary Toda language, there are a few words from Badaga (and some Indo-Aryan words borrowed through Badaga), Tamil, Hindi, and English. Because of the elaborate ritual structure, Toda language has developed an intricate system of naming of persons, water buffalos, and places. Like other languages, it has some culture-specific vocabulary—for instance, because of the importance of the water buffalo in the spiritual as well as mundane planes of their lives, we find words with very specific meanings such as: *malf-* 'buffalo gives a side glance before attacking.' The traditional songs (some of them are presently in their twilight stage) contain special words as well as word-formation processes. The most important component of a Toda song is a paired unit called *koṇ* (called song-units by earlier authors). An example of a *koṇ* is: *poṭy-terθ-poṇm # twïˑ-terθ-ïr* [box-having.opened-money # buffalo.pen-having.opened-buffalos] (just open the box and give money or open the buffalo-pen and give buffalos to anybody who asks>) 'to behave very generously.'

Todo, Akiyaso (b. 1915)

M McCaskey, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Tōdō Akiyasu (1915–1985) was born in Mie Prefecture, Japan, and grew up in China, where his father was stationed. He was directly descended from the 17th century Tōdō lords of Ueno, who were friends and patrons of the haiku poet Bashō (1644–1694). After graduating from Tokyo University in 1938, Tōdō joined the Japanese Foreign Service, and was assigned to study Chinese language and culture at an advanced level in Beijing. He was subsequently drafted into the Japanese Army, as a military Chinese language instructor.

After World War II, he became a graduate student of Chinese linguistics and philosophy at Tokyo

A number of verb bases also function as auxiliary verbs (Ax) in producing various modal forms. Some examples are: *kuty-ïs-s-pini* [*kuty*-'to embroider'-Ax-T-Pn] 'I knew how to embroider'; *pod-kïš-ïyi* [*pod*-'to come'-Ax-Pn] 'He could not come'; *noby-pïṭ-s-pini* [*noby*-'to believe'-Ax-T-Pn] 'I believed (him) wrongly,' *tïḏ-kuṛy-s-py* [*tïḏ*-'to eat'-Ax-T-Pn] 'You(sg) have completed eating'; *aˑfoṭ-kwïḏ-ïṭi* [*aˑfoṭ*-'to talk'-Ax -Pn] 'Don't talk to yourself,' *kïs-s-pod-s-si* [*kïs*-'to do' -Ax-T-Pn] 'He went on doing,' *köṭ-s-piˑ-č-či* [*köṭ* 'to be spoiled' -T-Ax-Pn] 'It will get spoiled.'

A set of suffixes derives verbal forms that are used as modifiers; for example, *tïḏ-fy oˑŁ* 'man who ate'; *tïḏ-θ oˑŁ* 'man who ate (more definite)'; *tïḏ-t oˑŁ* 'man who eats'; *tïḏ-p oˑŁ* 'man who can eat'; *tïn-oˑ-fy oˑŁ* 'man did/does not eat.' The suffix *-t* also derives a verbal noun as in: *nöw kïs-t* 'making a song' [*kïy-* ~*kïs-* 'to make, do'].

Vocabulary

Before the Todas came into contact with words from the languages from the plains such as Tamil, Hindi, and English, their borrowed vocabulary must have consisted of a few words from the language of their neighbors such as Badagas. In contemporary Toda language, there are a few words from Badaga (and some Indo-Aryan words borrowed through Badaga), Tamil, Hindi, and English. Because of the elaborate ritual structure, Toda language has developed an intricate system of naming of persons, water buffalos, and places. Like other languages, it has some culture-specific vocabulary—for instance, because of the importance of the water buffalo in the spiritual as well as mundane planes of their lives, we find words with very specific meanings such as: *malf-* 'buffalo gives a side glance before attacking.' The traditional songs (some of them are presently in their twilight stage) contain special words as well as word-formation processes. The most important component of a Toda song is a paired unit called *koṇ* (called song-units by earlier authors). An example of a *koṇ* is: *poṭy-terθ-poṇm # twïˑ-terθ-ïr* [box-having.opened-money # buffalo.pen-having.opened-buffalos] (just open the box and give money or open the buffalo-pen and give buffalos to anybody who asks>) 'to behave very generously.'

Tōdō Akiyasu (1915–1985) was born in Mie Prefecture, Japan, and grew up in China, where his father was stationed. He was directly descended from the 17th century Tōdō lords of Ueno, who were friends and patrons of the haiku poet Bashō (1644–1694). After graduating from Tokyo University in 1938, Tōdō joined the Japanese Foreign Service, and was assigned to study Chinese language and culture at an advanced level in Beijing. He was subsequently drafted into the Japanese Army, as a military Chinese language instructor.

After World War II, he became a graduate student of Chinese linguistics and philosophy at Tokyo

University, where he also taught Chinese language. His mentor in linguistics at Tokyo University was Professor Hattori Shirō, with whom Tōdō co-authored *Chūgen on 'in no kenkyū* a study of 14th-century Chinese phonology, in 1958 (Hattori and Tōdō, 1958). Shortly before that, Tōdō had completed a study of modern Chinese phonology, *Chūgokugo on 'in ron,* published in 1957. In 1960, after completing the 14-year doctoral program in linguistics, Tōdō became the head of the Chinese Literature Faculty of Tokyo University.

In the 1960s, Tōdō shifted his attention from phonology to the history and taxonomy of Chinese characters (*kanji*). Characters were traditionally arranged into 214 groups, with characters in each group sharing the same graphic classifying element. Several hundred phonetic elements also suggested the pronunciation of characters in which they occurred, but over time these elements had undergone so much phonological variation that members of character families sharing them often had quite divergent pronunciations. The 214 classifying elements of characters were also assigned to vague semantic categories, but over time these elements had also lost clear meaning boundaries in many cases. Scholars had traditionally analyzed many characters as combinations of these semantic and phonetic elements, but since these elements had become ill-defined, there were many inconsistencies in such analysis.

Tōdō found that ancient phonetic elements often had corresponding ancient semantic values, and that their graphic representations often suggested the same semantic values. He described these findings in *A study of the lexical origins of Kanji: research on word families in archaic written Chinese* (*Kanji no gogen kenkyū: jōko Kango no tango kazoku no kenkyū*) published in 1963. This was the beginning of Tōdō's lifelong lexemic and lexicological research on Chinese characters, yielding *kanji* dictionaries and other lexico-semantic studies based on this new mode of analysis.

During two years of political turbulence at Tokyo University in the late 1960s, Tōdō went to the campus every day and carried on with his research. After the disorder was quelled in 1970, he resigned his position because he felt overly harsh penalties were imposed on former student protesters. He accepted a teaching post at Waseda University and helped organize a private Chinese language and culture academy in Tokyo, which he headed until his death in 1985. He gave numerous lectures on Chinese language and linguistics on the national public NHK television network, published a number of books on Chinese language and culture, and became a well-known and popular authority on Chinese language and culture among the general public. He also continued to publish lexical and lexicographic studies, culminating in his monumental *Kanji-gen Character Dictionary,* published posthumously in 1988. This work continues to be a leading authoritative *kanji* dictionary, appearing in a series of revised editions up to the present day.

Togo: Language Situation

K Lébikaza, Département de Linguistique, Université de Lomé, Togo

© 2006 Elsevier Ltd. All rights reserved.

Togo was a former French colony and inherited French as the official language. In addition, 34 ethnic languages are spoken by Togo's population of 4.5 million. The country is in the special diglossic situation that characterizes many sub-Saharan African countries: a European language (French) is the official language and functions as the language of formal education and the medium of formal communication, while African languages are limited to a subsidiary role and used in informal domains (e.g., family, market place, in traditional activities, etc.).

Languages of Togo

It is difficult to give the exact number of indigenous languages spoken in Togo because of the well-known problem of distinguishing between dialects and languages. Furthermore, often ethnonyms are equated with glossonyms, although both realities do not always coincide. In the official population census statistics of 1981, we find 34 ethnonyms for a population of 3.9 million people:

> Adele (0.20%), Adja (3.12%), Ahlon (0.18%), Akebu (1.15%), Akposso (2.67%), Ana (Ife) (2.50%), Anlon/Aoulan (Igo) (0.07%), Anyanga (0.20%), Bariba/Tamberma (Be-tammaribe) (0.56%), Bassar (1.76%), Ehoue (0.12%), Ewe (23.19%), Fon (1.00%), Gurma (3.39%), Hausa (0.27%), Kabiye (13.79%), Konkomba (1.41%), Tem (Kotokoli) (5.75%), Kpessi (0.09%), Lamba (3.05%), Losso (4.10%), Ge (Mina) (5.66%), Moba (5.37%), Mossi (0.26%), Nago (Anago) (0.26%), Ngam-Gam (0.95%), Ouatchi (10.30%), Peda-Pla (0.40%), Peul (1.36%), Tchamba (0.97%), Tchokossi (Anufom) (1.18%), Yanga (0.29%), Yoruba (0.19%).

There are other ethnonyms not included in this list. Some small ethnic groups have been tacitly included in bigger groups which seem nowadays to be their natural allies. That is the case with the Adangme in the Ewe area, the Ntribu, located between the Adele and the Ewe, and the Biyobe in the Kabiye area.

With these last three included, Togo has a total of 37 ethnic groups. To be sure, population statistics for a particular ethnic group of cannot always be equated with the number of language speakers, as a given language may be spoken in several communities located in a linguistic continuum; for example Ewe among the communities in the Gbe continuum (i.e., Ewe 23.19%, Ouatchi 10.30%, Ge-Mina 5.66%, Adja 3.12%, etc.), and Kabiye in the Kabiye-Tem continuum (i.e., Kabiye 13.79%, Tem (Kotokoli) 5.75%, Lamba 3.05%, etc.). When one adds factors that favor a language being learned as second language, i.e., socioeconomic factors or a location near minor languages, one could find that more than 42% of the population speak Ewe and over 23% speak Kabiye. It is very difficult to establish with certainty how many people speak which language with what competence, so any statistics must be considered rough estimations. The 1981 census lists only six ethnic groups with over 5% of the population: Ewe 23.19%, Ouatchi 10.30%, Ge-Mina 5.66% (in the Gbe continuum), Kabiye 13.79%, Tem (Kotokoli) 5.75% (in the Kabiye-Tem continuum), and Ben (Moba) 5.37%.

The data help in the case of minor communities, i.e. those that are under 5% of the population, to evaluate the number of native speakers of individual Togolese languages. From 28 communities speaking different languages, 27 are under 5% for each, 25 under 3% for each , 17 under 2% for each. As their languages play a minor role in the communication of Togolese, it is clear that such languages are seldom learnt by other communities. Therefore, we can assume that the data for ethnic groups reflect the relative sizes of the groups of speakers of the minor languages. In percentage of the whole population of the country we find as very low percentages for these groups:

> Adele 0.2%, Ahlon (Igo) 0.18%, Akebu 1.15%, Anyanga 0.56%, Bariba and Temberma 0.56%, Fon 1.00%, Hausa 0.27%, Mosi 0.26%, Ngam-Ngam 0.96%, Fulani 1.36%, Tchamba 0.97%, Tchokossi 1.18%, Yanga 0.29%, Yoruba 0.19%.

All 14 of these linguistically different communities make up together just 9.13% of the Togolese population. When we consider the risk a language can run of becoming extinct because of the small size of its speaker population, we must exclude languages which are spoken by minorities in Togo, but at the same time are languages of wider communication in other countries. Thus Fon, Fulani, Hausa, Yoruba, and Mosi (More) cannot be included. The statistics referred to do not give any information about Dilo (language of Ntribu), Miyobe (language of Biyobe), and Adangme (language of Adangme). Numerically these groups are so small that they cannot even make 0.5% together, which is presumably the reason the national statistics fail to list them.

Another source for establishing the number of speakers of languages in Togo is the SIL Ethnolgue database. Table 1 is based on Ethnologue and gives the percentage of the total population for each Togolese linguistic community.

Table 1 Language speakers as a percentage of Togo's population of 4 397 000 (based on Ethnologue data)

1. Adele: 12 000 (0.26%) <Kwa>
2. Aja-gbe: 114 800 (2.53) <Kwa>
3. Akaselem/Tchamba: 34 300 (0.75%)<Gur>
4. Akebou: 40 700 (0.90%) <Kwa>
5. Akposso: 94 900 (2.10%) <Kwa>
6. Anii/Akpe/Basila: 4100 (0.09%) <Kwa>
7. Anufo/Tchokossi: 41 800 (0.90%) <Kwa>
8. Anyanga: 7200 (0.16%) <Kwa>
9. Bago: 6100 (0.13%) <Gur>
10. Bisa: 3000 (0.06%) <Mande>
11. Delo: 5400 (0.12%) <Gur>
12. Ewe: 861 900 (19.15%) <Kwa>
13. Fon-gbe: 35 500 (0.77%) <Gur>
14. Fulfulde: 48 200 (1.06%) <Atlantic>
15. Gen-gbe: 200 900 (4.46%) <Kwa>
16. Gurmancema: 120 500 (2.67%) <Gur>
17. Hausa: 9600 (0.21%) <Chadic Afroasiatic>
18. Ife: 74 000 (1.55%) <Benue-Congo>
19. Igo/Ahlon: 6300 (0.14%) <Kwa>
20. Kabiye: 700 000 (15.55%) <Gur>
21. Kambole: 20 000 (0.44%) <Benue-Congo>
22. Konkomba: 50 100 (1.11%) <Gur>
23. Kpessi: 3100 (0.068%) <Kwa>
24. Lama/Lamba: 117 400 (2.60%) <Gur>
25. Maxi-gbe: 25 300 (0.56%) <Kwa>
26. Moba/Ben: 189 400 (4.20%) <Gur>
27. Moore: 19 700 (0.43%) <Gur>
28. Nawdm: 145 600 (3.23%) <Gur>
29. Ngamgam: 33 500 (0.74%) <Gur>
30. Ntcham/Basar: 100 000 (2.22%) <Gur>
31. Sola/Miyobe: 1700 (0.037%) <Gur?>
32. Tamberma: 19 800 (0.44%) <Gur>
33. Tem: 204 100 (4.5%) <Gur>
34. Waci-gbe: 365 500 (8.12%) <Kwa>

The high language diversity in Togo is directly related to the geographical shape and position of the country; the dimensions of the country show a certain disproportion, with an east–west dimension of only 50 to 100 km against the south–north axis of 650 km. Linguistic diversity is particularly striking when one moves on the south–north axis. In fact, the country is located in that part of Africa referred to by Dalby (1980: 342) as "a zone of fragmentation" with a high linguistic complexity, stretching out from west to east across the African continent, from Senegal to Ethiopia and East Africa. Togo is a long but narrow band lodged in a linguistic zone where the diversity runs on the south-north axis: Gur languages in the northern part, Kwa languages in the southern part, intermediate languages between the two zones.

Official Language Policy and Language Attitudes

Togo has without any ambiguity an exoglossic language policy. French is the official language and also the only language that is ethnically neutral. Speaking French improves social status and allows international contacts, which are considered highly desirable. The relatively high literacy rate among the young portion of the population, the high prestige of French, and the strong diversity of indigenous linguistic communities combine to give the French language a real chance of becoming a lingua franca that will be accepted by all Togolese.

A language policy supporting indigenous languages in Togo was expressed in the School Reform Act of 1975: Ewe (a Kwa language) and Kabiye (a Gur language), spoken by the two numerically most important ethnic groups, were given the status of national languages. French remains the only official language. Two national languages zones were created: the Ewe zone in the south and the Kabiye zone in the north. The kindergarten was the domain of local maternal languages. Both chosen national languages had to be promoted and taught in schools according to the following schema: In the Ewe-zone, Ewe was to be taught as a subject in primary and secondary schools, and Kabiye as a subject in high schools, while in the Kabiye-zone, Kabiye was to be taught as a subject in primary and secondary schools, and Ewe as a subject in high schools.

Teachers were trained to teach these languages in primary and secondary schools. But the program did not cover all state schools and only few private schools agreed to introduce these languages as subjects. Lébikaza (1998) pointed out that the national languages program failed principally for the following reasons: the parents were not well informed and some of them did not accept that their children's curricula included learning the national languages; private schools were free to not apply the program; the taught languages were just optional subjects; few teachers were trained in these languages; and the program received increasingly less consideration and financial support.

In the government media (radio, television, newspapers) Ewe and Kabiye were used as national languages until 1990. After the National Conference of 1991, Radio Lomé and Radio Kara introduced news broadcasts in almost all African languages spoken in Togo. Kabiye and Ewe are given the most important broadcasting time. The minor languages are treated differently on the two stations. Radio Lomé takes strong minor languages like Miyobe (Sola) (with only 0.037% of the Togolese population), Anyanga, and so on into consideration; Radio Kara does not. Radio Kara uses one language within a linguistic cluster (i.e., Ewe for the Ewe-Waci-Gen cluster, Moba for the Moba-Gurmance cluster); Radio Lomé uses all members of these clusters. In fact Radio Lomé began,

under pressure of the ethnic-linguistic communities, to broadcast in almost all the languages of the country during the National Conference. Every politician was anxious to convince all the communities that they would not be excluded from the ongoing democratization process. The news is presented in Kabiye and Ewe for 30 minutes, three times a day, plus 10 minutes of notices and announcements), every other indigenous language is given five minutes of programming. One might say these are five symbolic minutes, but they provide time enough to let every community know that its language is present in the radio!

Radio Lomé (28 Languages)

Ewe: 1 hour 40 minutes daily
Kabiye: 1 hour 40 minutes daily

2 hours every day (total) for other African languages:

Adele, Aja-gbe, Akaselem/Tchamba, Akebou, Akposso, Anufo/Tchokossi, Anyanga, Ewe, Fon-gbe, Fulfulde, Gen-gbe, Gurmancema, Hausa, Ife (Ana-Ife), Kambole, Konkomba, Lama(Lamba), Miyobe(Sola), Moba(Ben), Moore, Nawdm, Ngangam, Ntcham (Basar), Tamberma, Tem, Waci-gbe.

Radio Kara (14 Languages)

Ewe: 1 hour 40 minutes per day
Kabiye: 1 hour 40 minutes per day

2 hours every day (total) for other African languages:

Akaselem/Tchamba, Akposso, Anufo/Tchokossi, Ewe, Fulfulde, Hausa, Konkomba, Lama(Lamba), Moba(Ben), Nawdm, Ntcham(Basar), Tamberma.

The national television station TVT gives only 15 minutes of news in Kabiye and Ewe daily. Sketches are regularly presented in both languages. No other Togolese language is used on national television. There are several private radio stations and some private television stations; they make use of national languages, mainly Ewe, Gen, Kabiye, and Tem. The use of one or more Togolese languages in these media depends on the objectives of their owners. The government daily newspaper *Togo Presse* is published in French and reserves a half page each to Ewe and Kabiye.

Language policy in Togo is designed by those in power to satisfy the majority of the population, at least emotionally, and to avoid frustrations. Indeed it seems out of question to propose a single national language policy in Togo. A multilingual approach is more suited to the Togolese reality (see Lébikaza, 1998, 2003, for discussion): Togolese languages should be used within their local domains as oral and written mediums and be complementary to French. Even the languages of small ethnic groups have an intensive intra-group use, reinforced sometimes by the existence of an urban center (i.e. Anufo in Mango, Ana-Ife in Atakpame, etc.). Each community in Togo preserves jealously its linguistic and cultural identity even if some of its members also speak other languages for extra-group purposes. The Togolese, more often women and children, learn the languages of the new locality where they settle. That is very important for informal interactions. It is therefore not rare to meet a Togolese who speaks two or more indigenous languages in addition to their own ethnic language. Candidates for a second language are either languages of the largest ethnic groups used in the urban centers, i.e., Ewe and Kabiye, or languages spoken by ethnic groups who are very active in trade and transport, i.e., Tem and Gen-gbe. The latter has an additional advantage in being the most important Togolese language in the capital Lomé.

Endangered Languages

Some 20 languages are spoken by fewer than 1% of the population of Togo. These languages are not necessarily considered endangered simply because of the small number of native speakers. A question arises as to how to determine whether a language is endangered. The number of speakers alone is not a sufficient indicator, and many minor languages are transmitted to younger generations. In many communities, loyalty to the community's language and culture are high, and so younger speakers learn minor languages in addition to the languages of wider communication, as well as French.

Tohono O'odham

M Miyashita, University of Montana, Missoula, MT, USA

© 2006 Elsevier Ltd. All rights reserved.

Tohono O'odham 'Desert People,' formerly known as Papago, belongs to the Tepiman (or Pimic) branch of the Uto-Aztecan language family, and is closely related to the Akimel O'odham (or Pima 'River People'). O'odham is spoken in Sonora, Mexico and Southwestern Arizona (Tohono O'odham, San Xavier, Ak Chin, Gila River, and Salt River). The estimated number of speakers is between 14 000 and 15 000 (Zepeda p.c. in Mithun, 1999).

In the early 1900s, Juan Dolores, a native O'odham speaker, documented the language with linguist J. Alden Mason (Mathiot, 1991). Dolores published collections of O'odham verbs (Dolores, 1913), noun stems (Dolores, 1923), and nicknames (Dolores, 1936). Mason and Dolores compiled their work into an O'odham grammar. Ken Hale (1959) wrote his dissertation, 'A Papago Grammar,' based on fieldwork with O'odham speakers, and Dean Saxton (1963) published an article on the O'odham phonemic system. Madeline Mathiot (1973) compiled an extensive dictionary with the grammatical usage. Saxton *et al*. (1983) published an English-O'odham/Pima and Pima/O'odham-English dictionary. Zepeda (1984), a native speaker, wrote a pedagogical grammar of Tohono O'odham. Some books portray O'odham songs (Bahr *et al*., 1997; Underhill, 1993). A number of recent articles in O'odham discuss the language from theoretical points of view (Hale, 1983; Hill and Zepeda, 1992; Fitzgerald, 1997, 1998, 2000, 2002; Miyashita, 2002; Truckenbrodt, 1999).

Many loanwords are from Spanish, and some are from other indigenous languages (Miller, 1990; Hill, 1998). Five major dialects are recognized: Totoguañ, Koló:di, Gigimai, Hú:hu'ula, Ko:adk, and Huhuwos (S'óobemakame) (Saxton, 1963; Saxton *et al*., 1983). There are generational and gender variations. Sentential conjunction such as *kuñ* '. . . , and I . . .' and *kup* '. . . , and you . . .' may be shortened to *n* and *p* (Zepeda, 1983). The former is more formal than the latter. Women use inhalation, or

Tohono O'odham

M Miyashita, University of Montana, Missoula, MT, USA

© 2006 Elsevier Ltd. All rights reserved.

Tohono O'odham 'Desert People,' formerly known as Papago, belongs to the Tepiman (or Pimic) branch of the Uto-Aztecan language family, and is closely related to the Akimel O'odham (or Pima 'River People'). O'odham is spoken in Sonora, Mexico and Southwestern Arizona (Tohono O'odham, San Xavier, Ak Chin, Gila River, and Salt River). The estimated number of speakers is between 14 000 and 15 000 (Zepeda p.c. in Mithun, 1999).

In the early 1900s, Juan Dolores, a native O'odham speaker, documented the language with linguist J. Alden Mason (Mathiot, 1991). Dolores published collections of O'odham verbs (Dolores, 1913), noun stems (Dolores, 1923), and nicknames (Dolores, 1936). Mason and Dolores compiled their work into an O'odham grammar. Ken Hale (1959) wrote his dissertation, 'A Papago Grammar,' based on fieldwork with O'odham speakers, and Dean Saxton (1963) published an article on the O'odham phonemic system. Madeline Mathiot (1973) compiled an extensive dictionary with the grammatical usage. Saxton *et al*. (1983) published an English-O'odham/Pima and Pima/O'odham-English dictionary. Zepeda (1984), a native speaker, wrote a pedagogical grammar of Tohono O'odham. Some books portray O'odham songs (Bahr *et al*., 1997; Underhill, 1993). A number of recent articles in O'odham discuss the language from theoretical points of view (Hale, 1983; Hill and Zepeda, 1992; Fitzgerald, 1997, 1998, 2000, 2002; Miyashita, 2002; Truckenbrodt, 1999).

Many loanwords are from Spanish, and some are from other indigenous languages (Miller, 1990; Hill, 1998). Five major dialects are recognized: Totoguañ, Koló:di, Gigimai, Hú:hu'ula, Ko:adk, and Huhuwos (S'óobemakame) (Saxton, 1963; Saxton *et al*., 1983). There are generational and gender variations. Sentential conjunction such as *kuñ* '. . . , and I . . .' and *kup* '. . . , and you . . .' may be shortened to *n* and *p* (Zepeda, 1983). The former is more formal than the latter. Women use inhalation, or

pulmonic ingressive airstream, in discourse for intimate interactional purposes (Hill and Zepeda, 1999).

The Alvarez-Hale writing system (Alvarez and Hale, 1970) is the official orthography of the Tohono O'odham Nation (Zepeda, 1983). Dictionaries by Mathiot (1973) and Saxton *et al.* (1983) use their own systems and are different from the Alvarez-Hale system (Zepeda, 1983; Miyashita and Moll, 1999).

Zepeda (1983) describes that O'odham exhibits 19 consonants: *b, c (= tʃ), d, ḍ (= ɖ)*, *g*, *h*, *j (= dʒ)*, *k*, *l (= ɭ)*, *m*, *n*, *ñ*, *ŋ*, *p*, *s*, *ṣ (= ʂ)*, *t*, *w*, *y (= j),* and asymmetric five vowels *i*, *e* (= *ɨ*), *u*, *o*, *a* . Although minimal pairs are rarely found, long and short vowels are phonemic (Hale, 1959). For example, *hik* 'navel' vs. *hi:k* 'cut,' *ta:tk* 'feel' vs. *tatk* 'the root of a plant.' There are extra-short (or aspirated, voiceless) vowels marked with a breve [ĭ] in the orthography. An additional example, *toki* 'cotton' vs. *go:kĭ* 'footprint.' Allophonic variations appear in native words. Phonemes *t d n ḍ*, and *ṣ* appear as *c j ñ l*, and *s* before */i/*.

The stress falls on an initial syllable, e.g., *músigo* 'musician.' Prefixes do not bear a stress, e.g., *ha-wápkon* 'them-wash.' Secondary stress appears in polymorphemic words (Fitzgerald, 1997). Some loanwords are noninitially stressed, e.g., *paló:ma* 'dove < Spanish *paloma*.'

Nouns and verbs undergo partial reduplication for plural and/or distributive indications, e.g., *gogs* → *gogogs* 'dog(s).' *him* 'walking sing.' → *hihim* 'walking pl.', etc. Some words do not reduplicate, e.g., *cicwi* 'playing.' (Zepeda, 1984; Hill and Zepeda, 1998). Truncation forms a perfective verb by dropping the last consonant of an imperfective verb, e.g., *o'ohan* 'writing' → *o'oha* 'wrote.' This does not apply to a vowel-final word, e.g., *cicwi* 'playing' → *cicwi* 'played,' *si'i* 'sucking' → *si:* 'sucked.'

Person/number of possessives is indicated by a prefix, except for third person singular, which is a suffix (Zepeda, 1984). Possessed nouns are classified into alienable and inalienable categories. Alienable nouns are analyzed as either they having been previously unowned or as being related to sequential human ownership (Bahr, 1986). As shown in (1) and (2), an alienable noun must have the suffix *-ga*, and an inalienable does not.

(1) ñ-je'e
1.sing.POSS-mother
'my mother'

(2) gogs-ga-j
dog-alienable-3.sing.POSS
'his or her dog'

O'odham is a nonconfigurational language. All six orders (SOV, SVO, OSV, OVS, VSO, and VOS) are possible for a transitive sentence without meaning alteration (Zepeda, 1984; Miyashita *et al.*, 2003). Pragmatic status may correlate the word order (Payne, 1987). Any nonpronominal noun must follow a particle called a *g*-determiner, except when it is sentence-initial. A sentence must have an auxiliary (AUX), which must be in the second position of the sentence as only one restriction regarding the configuration (Zepeda, 1984).

(3) Wakial 'o ceposid g haiwan. (SVO)
cowboy. AUX. branding DET cow.
sing 3.sing sing
'The cowboy is/was branding the cow.'

(4) Ceposid 'o g wakial g haiwan. (VSO)
branding AUX. DET cowboy. DET cow.
3.sing sing sing
'The cowboy is/was branding the cow.'

AUX indicates the subject's person and number, and a verb prefix indicates that of the object. However, as shown in sentences (3) and (4), any third person singular argument has no overt indication regarding the grammatical relation. Although there is no overt case marking, O'odham may be an ergative language because a reduplicated intransitive verb agrees with the plural subject, while a reduplicated transitive verb agrees with the plural object in a sentence (Zepeda, 1983; Miyashita, 2002).

Verbal aspects are distinguished between completed and continued actions (Dolores, 1913; Zepeda, 1983). Tense is divided into future and nonfuture. Imperfective present and past are not grammatically distinguished. Future is marked by a particle *o* with perfective AUX. Future imperfective sentences are formed with the perfective AUX, the imperfective verb, and usually the suffix *-d/-ad* on the verb.

O'odham kin terms show the equilateral system (Saxton *et al.*, 1983). Siblings and cousins are the same, *ṣe:pij*. Parents' siblings have eight distinct terms depending on the gender, age, and lineage. Grandparents have four distinct terms. Great-grandparents have one term, *wi:kol*. Great-great-grandparents have the same term as siblings, *ṣe:pij*. The term for 'child' is distinct depending on the gender of the parent rather than of the child.

Tok Pisin

S Romaine, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Tok Pisin (from English *talk pidgin*) is an English-lexicon pidgin spoken by approximately three-quarters of Papua Guinea's approximately 5 million inhabitants. It is not only the lingua franca of the entire country, with its 800 some indigenous languages, but it is also the language spoken by the most people in the South Pacific today. It is closely related to and mutually intelligible with Pijin in the Solomon Islands and Bislama in Vanuatu. All three varieties of Melanesian Pidgin owe their origins to the Queensland sugarcane plantations to which as many as 100 000 workers from these three countries were recruited during the 19th century. Men with mutually unintelligible village languages found themselves living and working together, as well as needing to communicate with their English-speaking plantation

Tok Pisin

S Romaine, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Tok Pisin (from English *talk pidgin*) is an English-lexicon pidgin spoken by approximately three-quarters of Papua Guinea's approximately 5 million inhabitants. It is not only the lingua franca of the entire country, with its 800 some indigenous languages, but it is also the language spoken by the most people in the South Pacific today. It is closely related to and mutually intelligible with Pijin in the Solomon Islands and Bislama in Vanuatu. All three varieties of Melanesian Pidgin owe their origins to the Queensland sugarcane plantations to which as many as 100 000 workers from these three countries were recruited during the 19th century. Men with mutually unintelligible village languages found themselves living and working together, as well as needing to communicate with their English-speaking plantation

managers. A form of pidgin English served this purpose. When the labor trade ended in 1905, most of the workers went back to their countries of origin, taking with them knowledge of this Queensland Plantation Pidgin. In these highly multilingual countries, pidgin served the useful internal function of communicating across ethnolinguistic boundaries. Social conditions were thus conducive not just for the retention and spread of the pidgin but also for its stabilization and subsequent creolization.

Today, Tok Pisin is used across Papua New Guinea's social spectrum, known by villagers and government ministers alike. It is the most frequently used language in the House of Assembly, the country's main legislative body, and the constitution recognizes Tok Pisin as one of the national languages of Papua New Guinea. Tok Pisin has become the main language of the migrant proletarian and the first language of the younger generation of town-born children, where it has creolized (i.e., become a creole). Tok Pisin is also one of the few pidgin and creole languages to have undergone considerable standardization because missionaries realized its potential early on as a valuable lingua franca for proselytizing among a linguistically diverse population and began using it for teaching. Most printed material is still religious; the Bible has been translated into Tok Pisin. However, the language is used to some extent in radio and television broadcasting, especially in interviews and news reports. The weekly Tok Pisin newspaper, *Wantok,* has a readership of over 30 000. Until recently, English was the only official language of education in Papua New Guinea despite the fact that few children enter school knowing it. However, education reforms have allowed communities to choose the language to be used in the first 3 years of elementary education, and many have chosen Tok Pisin.

The lexicon of Tok Pisin is mainly English (79%); Tolai (Kuanua), an indigenous language, has contributed 11%, other indigenous languages 6%, German 3%, and Malay 1%; there is also a handful of words from other European languages such as Portuguese/Spanish (e.g., *save* from Portuguese/Spanish *sabir/saber* 'to know/knowledge'). English borrowings provide the most important source of new vocabulary. Even frequently used words such as *kiau* 'egg' from Tolai are increasingly being replaced by or used alongside the English *egg*. Likewise, some of the German vocabulary in the language (e.g., *beten* 'pray'), dating from the period of German colonial rule (1884–1914) of part of the country, is giving way to English. The phonology of individual speakers of Tok Pisin varies from a core system that is shared by all speakers of the language and is similar to that of the indigenous substrate languages to a highly anglicized phonology that makes the most of English consonant and vowel distinctions. Tok Pisin has little morphology, although it has acquired some derivational and inflectional morphology in the course of its expansion. The suffix-*pela* is used to form the plural of the first- and second-person pronouns (e.g., *yu-pela* 'you plural'); it also marks a subset of monosyllabic attributive adjectives, demonstratives, and cardinal numerals (e.g., *dis-pela tu-pela pis* 'these two fish(es)'). Transitive verbs are marked with the suffix-*im*.

em	i	lus-im	dis-pela	ples
3.SING	PRED	leave-TRANS	this-DEM	place/village

'he/she/it left this place/village'

(Here, PRED stands for predicate marker.) Some grammatical distinctions reflect the influence of the substrate indigenous languages; in the personal pronoun system, different pronouns are used for inclusive (i.e., speaker + hearer) and exclusive (i.e., speaker + other(s), not including hearer). Compare *yumi* 'we (inclusive)' with *mipela* 'we (exclusive).'

Full lexemes are often used to express grammatical categories such as case, number, gender, tense, mood, and aspect, which in other languages are expressed by inflectional morphology; these distinctions are, however, not always obligatory. This is especially true for tense, mood, and aspect. The normal way of indicating past time is through use of the unmarked verb form, but *bin* (from English *been*) may be used.

ol	i	bin	adopt-im	liklik	meri
3.PL	PRED	PAST	adopt-TRANS	little	girl

'they adopted a/the little girl'

Sometimes *bin* is used in conjunction with *pinis* (from English *finish*) to mark completed actions in the past as a kind of perfective marker.

tim	bilong	Mormads	i	bin	win-im	pinis
team	of	Mormads	PRED	PAST	win-TRANS	PERF

'the Mormads team has won (the grand netball final)'

The meanings of immediate and remote future, prediction, intention, and irrealis may be expressed by clause-initial or preverbal *bai,* which has almost entirely replaced the earlier form *baimbai* (from English *by and by*). Pronominal subjects tend to take clause-initial *bai*, and noun phrases tend to take preverbal *bai*. Preverbal position is fast becoming the preferred order, although there are regional and stylistic differences.

mi	bai	go
1.SING	FUT	go

'I will go'

Tok Pisin has SVO word order; there is no copula and negation is preverbal (*mi no save* 'I don't know'). There is no inversion for questions.

yu-pela	gat	brus	a?
2-PL	have	tobacco	Q

'do you (plural) have tobacco?'

Tokelau: Language Situation

R Hooper, University of Auckland, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Tokelau comprises three atolls situated 500 km north of Samoa. Under New Zealand administration since 1926, it is in UN terms, a "non self-governing territory." It is expected that the people will eventually make an act of political determination and Tokelau will become "self-governing in free association with New Zealand." The language is spoken by approximately 7000 people. About 1500 live in the atolls and over 6000 in New Zealand. In addition there are some Tokelauans living in Australia, Hawaii, and the West Coast of the United States. Little is currently known about language maintenance in those areas.

Tokelauan belongs to the Polynesian branch of the Austronesian language family. Both long-standing and more recent subgrouping theories place it closest to the languages of Samoa and Tuvalu. The phonology follows the typical Polynesian pattern. There are five vowels, /i, e, a, o, u/, which can be short or long. The consonants are /p, t, k, f, h, v, l, m, n, g [=ŋ] /. The orthography is phonemic, except that long vowels are not distinguished by most Tokelauan writers. The macron is used by linguists and in some published Tokelauan material. The grammar has many features in common with other western Polynesian languages, including ergative case marking. Hooper (1996) is a short general description of the language.

Since the introduction of Christianity in the 1860s until 25 to 30 years ago, Samoan was the language of the church and schools, and in most contexts the only written language, resulting in some Samoan influence on the lexicon. Tokelauan oral culture was maintained, and adults were bilingual in Samoan and Tokelauan. In the 1960s an orthography was developed and the schools started to introduce instruction in writing and reading Tokelauan. It is now the language of the church and administration and is used in all contexts in island life. Hooper and Huntsman (1992) give a detailed history of Tokelau language use.

From the early 1960s onward, due to population pressures in the atolls, many Tokelauans migrated to New Zealand. For the second- and third-generation Tokelauan New Zealanders, some of whom are now attending tertiary institutions, language maintenance is problematic. In 1996 53% of Tokelauans in New Zealand were able to hold 'an everyday conversation' in their native language; by 2001 this had declined to 44%. Of that group, 71% were born in Tokelau. The decline is partly a result of the youth of the New Zealand Tokelau population: in 2001 43% were under 15 years of age. Church services continue to use Tokelauan, and there are two licensed Tokelauan early childhood education centers, in the Auckland and Wellington regions. Developments in the area of print culture include the *Tokelau dictionary* (1986); a Catholic missal; a Protestant hymnal; numerous publications by the New Zealand Ministry of Education for use in primary schools, and various items such as legal statutes and civil service reports circulated in photocopied and electronic forms. Bible translation is an ongoing project, and the four Gospels have already been translated and published.

Tokieda, Motoki (1900–1967)

R Washio, University of Tsukuba, Ibaraki, Japan

© 2006 Elsevier Ltd. All rights reserved.

Motoki Tokieda, one of the most influential, and controversial, scholars in the native tradition of Japanese linguistics, was born in downtown Tokyo on December 6, 1900. Strongly attracted to the Japanese language as a teenager, he had already determined what his life's work would be when he entered Tokyo Imperial University. His graduation thesis, completed in 1924, was a reexamination of the history of Japanese linguistics in the early modern period, with focus on the *Kokugaku* ('national learning') school of thought and the development of their 'consciousness' of language. In 1927, Tokieda was appointed to the Faculty of Law and Literature at Keijo Imperial University, which was established in Seoul, Korea by Imperial Japan in 1924. He was promoted to Professor in 1933. In 1943, two years before the end of World War II, he returned to Japan and succeeded Shinkichi Hashimoto as Professor of Japanese linguistics at Tokyo Imperial University. After his retirement from this position in 1961, he served as Professor at Waseda University in Tokyo. Tokieda died in Tokyo on October 27, 1967.

Tokieda had a great impact on Japanese linguistics with descriptions and analyses of Japanese based on his Process Theory of Language (PTL), which views language as the psychological process of communication. PTL has been and still is a topic of discussion and controversy in Japan, for its own sake as well as for the role it played in Tokieda's attack on Saussure. In his *Kokugogaku genron* ('Fundamentals of Japanese Linguistics') published in 1941, Tokieda contrasted PTL with Saussure's theory of language, severely criticizing the thoughts expressed in *Cours de linguistique générale* (or, perhaps more accurately, in its Japanese translation by Hideo Kobayashi). Tokieda's critique of Saussure invited countercritiques, to many of which Tokieda replied, including the one from the eminent linguist Shirō Hattori, which led to the famous Tokieda–Hattori debate in 1957. Hattori claimed among other things that Tokieda had misunderstood Saussure because he had grasped crucial notions like *une entité psychique* in terms of their Japanese translations, a point that contributed to the unusual expansion of the scope of the discussion – from the validity of PTL to the correctness of Tokieda's and Hattori's interpretations of the *Cours*, and even to the reliability of the Japanese translation. Since scholars outside of Japanese linguistics also participated in this extended debate, Tokieda has come to occupy a unique position among traditional Japanese linguists: he is probably the only one in this tradition who has been widely cited by philosophers and other non-linguists as well as by those linguists who would otherwise not have paid much attention to the traditional school of Japanese linguistics. In the latter school, Tokieda has

Toma, Peter (b. 1924)

F Katada, Wasada University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Peter Paul Toma, a linguist researcher for machine translation (MT) and one of the most prominent pioneers of MT, was born on July 10, 1924, in Hungary. In 1945 he became a refugee and arrived in Bavaria, Germany, where his multilingual competency in Hungarian, English, and German enabled him to function as a liaison between the U.S. Third Army and the many Hungarian refugees. In 1952 he immigrated to the United States, and he became a citizen in 1957, a year after he obtained a steady job in physics at the California Institute of Technology. About the same time the Institute received its first computer, a Datatron 205. Toma, among the first to take the computer course, realized immediately the potential for language translation and volunteered to spend night after night at the computer, programming and debugging his first system.

In 1958 Toma joined the Georgetown University MT project (until 1961) and developed the SERNA (*S Russkogo Na Angliskij* 'From Russian to English') system. Subsequently, at Computer Concepts Inc. in Los Angeles, he developed the AUTORAN and TECHNOTRAN systems. While politics and the 1966 ALPAC Report virtually 'killed' MT in the United States, Toma demonstrated his two systems successfully in Germany, mostly at the University of Bonn, from which he received his Ph.D. (1970) in communication and computer science. The high-level European recognition and the fact that he received a grant from the prestigious German Science Foundation moved the U.S. Air Force to support Toma's latest invention at the time, SYSTRAN (System Translation); it has been installed at Wright Patterson Air Force Base since 1969. Two companies developed and marketed SYSTRAN: LATSEC Inc. (for the U.S. government) and World Translation Center Inc. (for outside the government); Toma established each in La Jolla, California, in 1968 and 1975, respectively.

In 1985 Toma sold SYSTRAN to Jean Gachot to be able to finance a high-level Conflict Resolution Symposium in New Zealand, to bring East and West closer together. Since then he has also become an expert in longevity and related sciences, yet his passion for MT has remained unchanged. On August 8, 2003 in Budapest, Toma met his wife Réka, who currently works with him and coordinates the implementation of his latest inventions: the VOXTRAN speech translation system and the Personal Translator (PT). World-renowned scientists, experts, and a trained staff in Budapest are participating in this enterprise with enthusiasm.

Tone in Connected Discourse

Y Xu, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

In connected discourse, lexical tones in a sentence have to be said in quick succession, frequently with no pauses in between. In addition to tone, a sentence also carries many other communicative functions that either use pitch as their primary or secondary carrier or change pitch inadvertently. As a result, the acoustic manifestation of tone, mainly in the form of fundamental frequency (F_0) contours, rarely resembles its underlying form. A clear understanding of tone is therefore impossible without comprehending the effects of these factors on the acoustic form of tone. This article discusses the realization of tone in connected discourse in terms of the interaction between tone and other pitch-modifying factors. The discussion is mainly based on data from Mandarin, for which extensive experimental data have been collected in recent years.

How Are Tones Produced in Succession?

In connected speech in a tone language, adjacent syllables frequently have different tones. One of the most basic issues concerning tone in discourse is how a sequence of tones are articulated in succession. Is the shift from one tone to the next instantaneous or fast enough so that the shifting period is negligible? If the shift is not instantaneous, where does it occur? Is there a time interval specially reserved for the tonal shift? Answers to these questions can be found through systematic comparisons of sentences with different tonal compositions. Figure 1 displays time-normalized F_0 contours of Mandarin five-syllable sentences. In each panel, the tones of all syllables are held constant except those of syllable 2, which alternate across high (H), rising (R), low (L), and falling (F). Several direct observations can be made. First, although the tone of syllable 3 is the same in each panel, the F_0 trajectory varies extensively when the tone of syllable 2 changes. Second, there is nevertheless consistency about the tones in syllable 3. In each panel, the four F_0 curves in the syllable gradually converge to a quasi-linear configuration appropriate for the tone: high-level for H, rising for R, and falling for F, as illustrated by the short straight dashed lines. Assuming that these quasi-linear trajectories resemble some sort of the desired goals for the tones, the approximation of each of them starts roughly from the onset of syllable 3 and ends approximately at the offset of syllable 3, whether the converging configuration is a slope or a horizontal line. These

Figure 1 Mean F_0 contours of Mandarin 5-tone sequences in sentence. Each curve is a time-normalized average across 24 repetitions by four male speakers (Xu, 1999). (A–C) H, R, and F (in syllable 3) are preceded by four different tones and followed by H. (D) R in syllable 3 is followed by L. Vertical lines indicate syllable boundaries. The short dashed lines depict hypothetical underlying pitch targets. The audios are samples of individual sentences. Their F_0 curves may not precisely match those shown here. With permission from Elsevier Inc.

observations suggest the basic mechanisms of tone implementation in connected speech. First, the transition between adjacent tones is not instantaneous. Rather, it takes a long time. Second, despite this fact, no time intervals are reserved just for the tonal transitions. Instead, the transition toward each tone occurs *in situ* (i.e., during the syllable to which the tone is designated). Third, each transition starts at the beginning of the host syllable and terminates at the end of the syllable. Thus, the F_0 of an entire syllable constitutes a continuous movement toward the ideal pitch pattern of the tone it hosts. In other words, the approximation of the underlying pitch target of a tone is synchronized with its host syllable.

The sluggishness of the shift between adjacent tones is directly related to a basic articulatory constraint – the maximum speed of pitch change. This speed can be expressed with the following linear equations based on data reported in Xu and Sun (2002):

$$t = 89.6 + 8.7d \quad \text{(raising)} \tag{1}$$

$$t = 100.4 + 5.8d \quad \text{(lowering)} \tag{2}$$

where t is the amount of time (ms) it takes to complete the pitch shift, and d is the size of pitch shift in semitone (st). According to Eqs. (1) and (2), it takes approximately 124 ms to either raise or lower pitch by 4 st. As can be seen in Figure 1, the difference between two adjacent tones is often close to or greater than 4 st ($1\ \text{st} = 12 \times \log2\ (F_0/F_{0\text{reference}})$). In connected speech, the duration of a syllable is very short compared to the minimum time needed to make the tonal transitions. In Mandarin, for example, the average syllable duration is approximately 180–215 ms (Duanmu, 1994; Xu, 1999). This means that to make a single pitch shift of 4 st, the greater half of a syllable has to be used just for the transition even at the maximum speed of pitch change. As can be seen in Figure 1, if the tone is R or F, often two pitch movements have to be made within one syllable. According to Eqs. (1) and (2), there is barely enough time for any two pitch movements within a syllable 180–215 ms long. Indeed, in producing these tones the maximum speed of pitch change is frequently approached (Xu and Sun, 2002). In fact, even the maximum speed is often not fast enough. This is evident from the apparent 'undershoot' in syllable 3 in Figure 1: when the tone of syllable 2 ends low, the F_0 peak in F becomes lower, and when the tone of syllable 2 ends high, the F_0 valley in R becomes higher. Furthermore, the location of these F_0 turning points also varies: the greater the F_0 excursion in the early part of the syllable, the later the turning point.

The tonal undershoot and the delay in the syllable-internal turning points further highlight the synchrony between tone and syllable. Without such synchrony in the HLF sequence, the transition toward F could have started earlier, given that L is more easily approached because only a single pitch movement is involved. Apparently, no microadjustment of tonal alignment is made and the synchrony between tone and syllable is maintained, often at the expense of full realization of the tone.

These facts suggest syllable-synchronized sequential (pitch) target approximation as the basic mechanism of tone implementation. A pitch target is an ideal pitch trajectory associated with a tone. A target can be rather simple, as illustrated by the short dashed lines in Figure 1, but still capable of leading to a complex surface F_0 contour due to the target approximation process. It can be a static register such as [high], [low], or [mid], which probably underlies a tone such as H, L, or M. Targets can also be dynamic, such as [rise] and [fall]. For these targets, both the slope and the relative height are part of the articulatory goal. Such targets may underlie tones such as R and F.

A further implication of syllable-synchronized sequential target approximation under the constraint of the maximum speed of pitch change is that if the duration of a syllable in a language is routinely shorter than that needed for two F_0 movements within a syllable, it may become impossible for that syllable to carry contour tones. Indeed, research has revealed a close relation between the occurrence of contour tones and average vowel length (which is closely related to syllable length) in many languages (Duanmu, 1994; Zhang, 2002).

Finally, if the contextual F_0 variation of tone as shown in Figure 1 is viewed in terms of the influence of adjacent tones on each other, there is extensive carryover assimilation but little anticipatory influence. If any, the anticipatory influence is mostly dissimilatory, as can be seen in Figure 1: the F_0 of H in syllable 1 is higher whenever the tone of syllable 2 has a low F_0 point. Such dissimilation has been found in several languages, including Mandarin, Thai, Yoruba, and Igbo. However, its underlying mechanism is unclear.

Dynamic versus Static Targets

A long-standing discussion in tone research concerns whether a tone such as R or F is composed of successive level components so that the underlying composition is actually LH or HL or a single contour component that somewhat resembles the actual F_0 curve. The constraint of the maximum speed of pitch change makes it unlikely that the actual F_0 contour directly corresponds to an underlying

Figure 2 Hypothetical F_0 trajectories (curved lines) that asymptotically approach either two consecutive static targets (solid lines) or a single dynamic target (dashed lines). In (A) the previous tone ends high, whereas in (B) the previous tone ends low. With permission from Elsevier Inc.

configuration. On the other hand, whether or not two separate underlying components are involved can be tested in terms of whether a single target or two successive ones are being implemented. Figure 2 illustrates how such distinction can be made. If a particular tone consists of two elements, as indicated by the low and high level bars in Figure 2A, a clear transition should occur between the two. Thus, a LH combination should result in an F_0 contour like the solid curve in Figure 2A, which approaches the [low] and [high] targets in succession. If, however, the target is unitary but dynamic, like the dashed slanting line in Figure 2A, the resulting contour should have the shape of the dashed curve. If the previous tone happens to end low, then the F_0 contours resulting from two static targets or one dynamic target may look like the solid or dashed curve in Figure 2B, respectively. A further test is that the distinction between consecutive static targets and unitary dynamic target should become even more apparent when (i) the syllable duration is increased and (ii) the tone is emphasized and hence given greater articulatory effort for implementing its target(s).

A case in point is R and F in Mandarin. When spoken at a slow rate, the F_0 contour of R resembles the dashed rather than the solid curves in either Figure 2A or Figure 2B, and the most dynamic portion of the F_0 contour becomes increasingly later as the syllable duration increases. Furthermore, when under focus (i.e., being emphasized), the dynamic portions of R and F in Mandarin occur even later in the syllable, as can be seen in Figure 3, instead of exhibiting clear separation of two static components as do the solid lines in Figure 2.

The evidence thus suggests that tones such as R and F in Mandarin are associated with dynamic [rise] and [fall] as pitch targets. On the other hand, of course, the existence of dynamic tonal targets does not mean that any contour-like tone is underlyingly dynamic. It is also possible for a tone to be composed of two successive pitch targets. For example, the citation form of L in Beijing Mandarin may indeed consist of two components: a [low] followed by either a static [mid] or [mid-high] or a dynamic [rise]. (Further research is needed to determine which is more likely the case.) It is thus an empirical question whether a particular contour-like tone in a language or dialect has underlyingly static or dynamic target(s).

Tonal Variation Due to Change of Underlying Pitch Target

The understanding of the basic mechanisms of producing tones in succession can also help us better identify cases in which the targets themselves are changed. Such changes are often referred to as tone sandhi. The sandhi may be prompted by different triggers, some related to particular tonal contexts and some to morphological or syntactic functions (*see* **Tone: Phonology**). In the case of Mandarin L-sandhi, for example, L becomes very different when followed by another L than when followed by other tones, as can be seen in Figure 4A. Figure 4B shows that the surface form of such L variant is very similar in shape to that of R. Indeed, native listeners cannot distinguish LL from RL (Peng, 2000; Wang and Li, 1967).

What is most striking about this kind of tonal variation is that, as can be seen in Figure 4A, the sandhi L starts to differ very early in its host syllable from the non-sandhi L, and the latter exhibits virtually no sign of anticipating the following tone. This suggests that what happens to L in anticipation of an upcoming L is that its pitch target is changed before execution, and such change does not alter

Figure 3 Mean F_0 contours of Mandarin tone sequences HFRLH (A) and HRFHH (B) spoken with focus in different positions. The curves are time-normalized F_0 averaged across 24 repetitions by four male speakers. Data from Xu (1999). The audios are samples of individual sentences. Their F_0 curves may not precisely match those shown here. With permission from Elsevier Inc.

the process of syllable-synchronized sequential target approximation. In other words, once assigned, a sequence of pitch targets are just implemented one at a time – each during the time interval of its host syllable. No anticipatory target execution is involved.

Target alternation is not limited to anticipation of an upcoming tone; it can also happen after certain tones. In Yoruba, for example, H is known to become R after L, and L becomes F after H. It is not fully clear, however, whether these are genuine cases of target alternation or cases of carryover assimilation. Further research is needed.

Tonal Variation Related to Aspects of Target Execution

Whereas tones specify the pitch targets (which are subject to alternation, as just discussed) of individual syllables, other aspects of the target approximation process are left unspecified and, hence, available for manipulation to encode other communicative functions. These aspects include articulatory strength, syllable duration, and pitch range. The manipulation of these aspects has strong effects on the surface F_0 contours. In fact, F_0 variations due to some of these effects are often no smaller than those due to the lexical tones.

Tonal Variation Due to Articulatory Strength and Syllable Duration

Articulatory strength determines how quickly a pitch target is approximated, and syllable duration determines how much time is allotted to the approximation process. Other things being equal, therefore, greater strength enables a pitch target to be approached more quickly than weaker strength, and longer syllable duration allows a target to be more fully implemented than shorter duration. Thus, manipulation of strength or duration or both determines the extent to which a lexical tone is realized. Also, such manipulation can be used to encode certain communicative information.

Strength and Duration as Lexical Information In some tone languages, certain morphemes are considered to be phonologically toneless (*see* **Tone: Phonology**); for example, those morphemes in Mandarin that are said to bear the neutral tone. Also, L in Chichewa and M in Yoruba are believed to be unspecified for tonal values. Regarding where the F_0 values of these syllables come from, a popular view is that they are derived through interpolation between adjacent tones. Experimental data suggest, however, that interpolation is an unlikely process. Figure 5 shows Mandarin sentences containing three consecutive neutral tone (N) syllables. In Figure 5A, they are

Figure 4 (A) Mean F_0 contours of Mandarin L before (A) and after (B) four different tones. Adapted from Xu (1997). The audios are samples of individual sentences. Their F_0 curves may not precisely match those shown here. With permission from Elsevier Inc.

Figure 5 Mandarin sentences containing three consecutive neutral tone (N) syllables. In (A), they are preceded by four different tones. In (B), they are followed by either F or L. Data from Chen and Xu (2002). The audios are samples of individual sentences. Their F_0 curves may not precisely match those shown here.

preceded by four different tones and followed by F. In Figure 5B, they are preceded by H but followed by either F or L. In Figure 5A, the F_0 of the neutral tone syllables is substantially affected by the preceding tone. However, the influence gradually reduces as time elapses, and by the end of the third neutral tone, the four F_0 curves have almost converged. In Figure 5B, in contrast, the tone of the last syllable has virtually no influence on the preceding neutral tone. Thus, F_0 of the neutral tone could not have been derived from interpolation between the surrounding tones because the following tone makes no contribution to its F_0. Given that the carryover influence from the preceding tone is similar in nature as that seen in Figure 1, the F_0 convergence over the course of the neutral tone must be in the direction of an underlying pitch target associated with the neutral tone, which is probably a static [mid]. What makes the neutral tone really different from the full tones is likely to be weaker articulatory strength plus shorter syllable duration (approximately 60% of the length of full tone syllables), which would lead to both slower target approximation and greater undershoot.

Regarding how weak the strength can be, there have been suggestions that the level of articulatory effort is zero, and the F_0 movement during the neutral tone is due to relaxation to a rest position under the elastic force of the vocal folds. Note that such elastic force is available only if the vocal folds are stretched beyond their resting length during the production of the full tones. However, the vocal folds are typically much shorter during phonation than during rest (Hollien and Moore, 1960). Thus, whatever pitch target is associated with a neutral tone or its like, it is probably implemented with active muscle forces, although the forces can be quite weak at times.

Strength and Duration as Grouping and Demarcation Information In addition to lexical information, strength may also serve to group syllables into chunks and to group smaller chunks into larger ones. Such grouping is closely related to a hierarchical prosodic structure whose communicative function is not fully clear. What is determined by prosodic structure is the grouping relation among the linear sequence of syllables and words. It has been demonstrated that a syllable's ability to resist tonal coarticulation from adjacent tones is related to its prosodic strength (Shih and Sproat, 1992). Tones on prosodically weak syllables tend to have less extreme tone shapes or greater undershoot.

Figure 6 displays mean F_0 contours of consecutive R and F sequences with varying numbers of syllables

Figure 6 Mean F_0 contours of consecutive R and F sequences with varying numbers of syllables said in the middle of a carrier. The audios are samples of individual sentences. Their F_0 curves may not precisely match those shown here.

said in the middle of a carrier. The all-R and all-F sequences impose great pressure on tone production, as discussed previously, and hence would best reveal the strength differences among syllables. As can be seen in Figure 6, as the number of syllables increases, the magnitude of F_0 excursion decreases, which appears to be related to the insufficient increase in syllable duration as the group size becomes larger. Meanwhile, the magnitude reduction differs in various locations. However, in each case it is the first and last syllable in the group that are reduced the least. There thus appears to be an 'edge marking' effect. This line of research is still in its early stage, and much more needs to be learned about how exactly articulatory strength and duration are used by various functions.

Tonal Variation Due to Pitch Range Modification

Pitch range specifies the pitch interval within which each tonal pitch target is implemented. It is definable by two parameters: height and span. The effectiveness of pitch range manipulation has to do with the fact that the entire exploitable pitch range of human speakers is quite large, approximately 2 octaves in total (Fairbanks, 1959). This is more than twice as much as the range needed for lexical tones. Thus, even in a tone language there is room left in the pitch range for things other than lexical tones. From the perspective of the target approximation process, pitch range manipulation can be achieved by shifting the height of a pitch target without changing anything else about it. Pitch range manipulation has been put to use by languages for encoding functions such as focus, sentence type, and new topic (topic shift/turn-taking).

Focus Focus is a pragmatically motivated emphasis. For example, when the sentence 'John talked to Jane' is said in response to the question 'Who talked to Jane?' the word 'John' is naturally emphasized, hence 'focused.' In certain circumstances, speech sounds as small as a single segment can be put under focus (van Heuven, 1994). At the same time, focus is a global function. That is, with focus the speaker tries to indicate that a particular component of the utterance is highlighted against all other components. This is done by an asymmetrical pitch range manipulation about the focused item, as can be seen in Figure 7 as well as Figure 3. Specifically, a narrow focus is manifested through a tri-zone pitch range control: the pitch range of focused region is expanded, that of the postfocus region suppressed, and that of the prefocused region left largely the same as in utterances without narrow focus. Expansion means the pitch range is widened instead of only raised. The widening is the most obvious in Figure 3A, in which the low point of R becomes lower under focus. Tri-zone pitch range control by focus is quite widespread among languages, both tonal and nontonal, although it is not clear whether it is truly universal.

An interesting consequence of the tri-zone pitch range control is that a final focus (i.e., focus on the last word of a sentence) is not implemented effectively. This is clearly seen in both Figure 3 and Figure 7. As a result, final focus is also perceptually not well separated from no narrow focus.

Presumably, the on-focus pitch range expansion is conditioned by postfocus pitch range suppression: if the latter is not implementable (for there is no postfocus component), the former cannot be effectively implemented either.

Sentence Type: Statement versus Question Pitch range can be further modified by a function that may be referred to as sentence type. This function distinguishes question from statement and possibly also from continuation. A question is known to have an overall rising intonation, although it is also known that not all syntactic questions have a rising intonation. Although the F_0 difference between question and statement is the most obvious at the end of the sentence, more global patterns are also involved. In particular, the onset of the F_0 raising by question is conditioned by focus. Figure 8 shows mean F_0 contours of Mandarin question versus statement in sentences consisting of only H. In Figure 8a, either focus is on the sentence initial word or there is no narrow focus (neutral focus). In Figure 8b, focus is either sentence medial or sentence final. It is apparent that the divergence between statement and question starts from the focused word rather than from the beginning of the sentence or occurring only in the final word of the sentence.

The F_0 patterns in Figure 8 thus demonstrate that question intonation consists mainly of pitch range adjustments, and the adjustments are likely to be nonlinear over time, with greater increase toward the end of the question. The nonlinearity may explain why the final raising is typically much more prominent than in earlier regions. Similar to the nonlinear

Figure 9 Effects of voiceless consonants on the F_0 contours of Mandarin R and F produced after H and L. Each curve is an average across five repetitions, two carrier sentences, and seven female speakers. All curves are aligned to the syllable offset. Data from Xu *et al.* (2003).

F_0 raising in questions, the gradual F_0 lowering in statements is also likely nonlinear, with greater decrease toward the end of the statement.

New Topic (Topic Shift/Turn-Taking) Pitch range can be further modified by a function that affects the beginning of a sentence more than the end of the sentence. When a sentence is the very first in a conversational turn or a read paragraph, its onset F_0 can be extensively raised, sometimes by as much as an octave (Umeda, 1982). Although the details are not quite clear, this function also seems to affect the pitch range of a sentence nonlinearly, with a large F_0 raise near the beginning of the sentence and an F_0 descent afterwards that is fast at first but slows down later. The high initial F_0, often accompanied by increased intensity, probably helps to draw listeners' attention. As such, the function probably serves as a beginning signal for a new topic or a conversational turn.

The Effects of Pitch Range Manipulations Combined We have seen that although the local F_0 contours of individual syllables are mostly determined by the underlying pitch targets and their manner of implementation as related to articulatory strength and syllable duration, the relative height of the tones can still be extensively modified by focus, sentence type, and new topic. Note also that these functions, with the only exception of question intonation, all tilt F_0 downward toward the end of the sentence. Such tilting is in the same direction as the frequently reported tonal phenomenon known as downdrift. Thus, future research is needed to determine if downdrift is in any way related to these functions.

Inadvertent F_0 Variation

Inadvertent F_0 variation refers to F_0 changes caused by functions whose primary target of control is not F_0. Two types of inadvertent F_0 variations have been widely reported: vowel intrinsic F_0 and perturbation of F_0 by consonant. As their names indicate, the primary target of control is the articulation of the vowel or consonant rather than F_0 *per se*. Nevertheless, F_0 is inadvertently affected by the articulatory maneuvers involved.

Intrinsic F_0 of Vowel

Intrinsic vowel F_0 refers to the phenomenon that, other things being equal, different vowels are produced with different F_0 values. Such variation is mostly related to vowel height: the higher the vowel, the higher the F_0. The intrinsic F_0 difference is in the range of 1.65 st or 15 Hz (Whalen and Levitt, 1995). Intrinsic F_0 has been found in both tone and nontone languages. Being small in magnitude, it does not usually affect either the local or the global F_0 patterns in a significant way. There is also evidence that its

magnitude becomes smaller in connected speech (Ladd and Silverman, 1984). Nevertheless, with regard to systematic analysis of any effect on F_0 by other factors, intrinsic F_0 has to be taken into consideration.

Consonant Perturbation of F_0

A nonsonorant consonant perturbs F_0 in two ways. First, it interrupts the otherwise continuous F_0 flow. Second, it either raises or lowers the F_0 of the adjacent vowels. Although the F_0 raising and lowering have been widely known, the effect of F_0 interruption is often not carefully considered. In general, it has been taken for granted that because of the F_0 interruption, consonants are not part of the tone-bearing unit. Recent research, however, has found evidence that the voicing interruption does not really disrupt the pitch target approximation process as seen in Figure 1. Figure 9 displays the mean F_0 contours of Mandarin syllables /ma/, /da/, /ta/, and /sha/ spoken with R and F. Compared to the F_0 contours in /ma/, in which the transition toward the tonal target is visible, the F_0 curves in syllables with the voiceless consonants start late and have various amounts of local perturbations at the voice onset. Nonetheless, if these local effects are put aside, the F_0 curves in /da/, /ta/, and /sha/ look very similar to those of /ma/. Hence, by the time the apparent local effects are over, F_0 is already quite low in R but quite high in F. Therefore, the process of syllable-synchronized sequential target approximation remains the same whether or not voicing continues through the consonant. Thus, the effect of voiceless consonants is only to introduce rather local perturbations without changing the basic mechanism of tone production.

Introduction

The notion of speech prosody dates back to Monrad-Krohn's (1947) case study of a woman who was unable to produce the phonemic tone contrasts in her native Norwegian dialect, even though she retained considerable musical ability. Languages that exploit phonologically relevant variations in pitch at the syllable level are called tone languages (for review of the phonetics of tone languages, see Gandour (1994)). Tone languages are especially advantageous for exploring how speech prosody is mapped in the human brain. The focus here is on three major sources of evidence relevant to the neural substrates underlying tonal processing: dichotic listening studies, to assess hemispheric laterality effects; lesion-deficit studies, to assess tonal deficits in production or perception by unilateral brain-damaged adults; and functional neuroimaging studies, to assess normal adult tonal processing brain activity in the two brain hemispheres. Dichotic listening studies tell us which hemisphere predominates for a given function, lesion-deficit studies tell us what areas within a hemisphere are necessary for normal functioning, and brain imaging studies tell us what areas in either the left hemisphere (LH) or the right hemisphere (RH) participate in that function. From a historical perspective, the dichotic listening paradigm goes back about 40 years, lesion-deficit analysis has been used for almost 150 years, and functional neuroimaging has emerged within the past 20 years. This new analytical neuroimagery tool permits us to investigate in both hemispheres, the large-scale, widely distributed neural networks that underlie tonal processing in the normal functioning human brain.

Dichotic Listening

With the dichotic listening technique, two different auditory stimuli are presented at the same time, one in each ear (Hugdahl, 1999). Dichotic presentation of verbal auditory stimuli typically yields a right ear advantage (REA) when participants are requested to report what they hear on each trial. The standard explanation for the REA is that the contralateral auditory pathways suppress the ipsilateral pathways at the level of the brain stem, thus favoring the right ear input to the language-dominant LH. Information from the left ear has to be transferred across the corpus callosum in order to be processed in the LH. This transfer attenuates the available information, in addition to increasing the time it takes for the left ear signal to reach the language centers in the LH.

The RH, on the other hand, appears to be better at processing music and pitch contours in nonlanguage contexts (Zatorre *et al.*, 2002). This raises the question of how pitch contours are processed in the human brain when they signal differences in meaning at the lexical level. Tone languages provide a window for investigating hemispheric specialization of pitch processing in language vs. nonlanguage domains. By comparing dichotic perception of identical pitch contours in speech and nonspeech contexts, we are able to determine whether hemispheric specialization is driven primarily by complex physical cues or by domain-specific phonological functions.

The seminal dichotic perception studies of lexical tone focused on Thai (Van Lancker, 1980). Speakers of a nontone language (English), musically untrained and musically trained, served as control groups. Ear preferences were compared for three sets of stimuli: stimulus (1), a minimal set of Thai words distinguished by tone; stimulus (2), a minimal set of Thai words distinguished by initial consonant; and stimulus (3), a minimal set of hums distinguished by pitch changes homologous to stimulus (1). The Thai group showed a significant REA for both the tone words (stimulus (1)) and the consonant words (stimulus (2)), but no ear advantage for hums (stimulus (3)). English listeners, regardless of musical training, showed a REA for the consonant words of stimulus (2) only. Taken together, these findings suggest that pitch perception is lateralized to the LH when pitch variations

Introduction

The notion of speech prosody dates back to Monrad-Krohn's (1947) case study of a woman who was unable to produce the phonemic tone contrasts in her native Norwegian dialect, even though she retained considerable musical ability. Languages that exploit phonologically relevant variations in pitch at the syllable level are called tone languages (for review of the phonetics of tone languages, see Gandour (1994)). Tone languages are especially advantageous for exploring how speech prosody is mapped in the human brain. The focus here is on three major sources of evidence relevant to the neural substrates underlying tonal processing: dichotic listening studies, to assess hemispheric laterality effects; lesion-deficit studies, to assess tonal deficits in production or perception by unilateral brain-damaged adults; and functional neuroimaging studies, to assess normal adult tonal processing brain activity in the two brain hemispheres. Dichotic listening studies tell us which hemisphere predominates for a given function, lesion-deficit studies tell us what areas within a hemisphere are necessary for normal functioning, and brain imaging studies tell us what areas in either the left hemisphere (LH) or the right hemisphere (RH) participate in that function. From a historical perspective, the dichotic listening paradigm goes back about 40 years, lesion-deficit analysis has been used for almost 150 years, and functional neuroimaging has emerged within the past 20 years. This new analytical neuroimagery tool permits us to investigate in both hemispheres, the large-scale, widely distributed neural networks that underlie tonal processing in the normal functioning human brain.

Dichotic Listening

With the dichotic listening technique, two different auditory stimuli are presented at the same time, one in each ear (Hugdahl, 1999). Dichotic presentation of verbal auditory stimuli typically yields a right ear advantage (REA) when participants are requested to report what they hear on each trial. The standard explanation for the REA is that the contralateral auditory pathways suppress the ipsilateral pathways at the level of the brain stem, thus favoring the right ear input to the language-dominant LH. Information from the left ear has to be transferred across the corpus callosum in order to be processed in the LH. This transfer attenuates the available information, in addition to increasing the time it takes for the left ear signal to reach the language centers in the LH.

The RH, on the other hand, appears to be better at processing music and pitch contours in nonlanguage contexts (Zatorre *et al.*, 2002). This raises the question of how pitch contours are processed in the human brain when they signal differences in meaning at the lexical level. Tone languages provide a window for investigating hemispheric specialization of pitch processing in language vs. nonlanguage domains. By comparing dichotic perception of identical pitch contours in speech and nonspeech contexts, we are able to determine whether hemispheric specialization is driven primarily by complex physical cues or by domain-specific phonological functions.

The seminal dichotic perception studies of lexical tone focused on Thai (Van Lancker, 1980). Speakers of a nontone language (English), musically untrained and musically trained, served as control groups. Ear preferences were compared for three sets of stimuli: stimulus (1), a minimal set of Thai words distinguished by tone; stimulus (2), a minimal set of Thai words distinguished by initial consonant; and stimulus (3), a minimal set of hums distinguished by pitch changes homologous to stimulus (1). The Thai group showed a significant REA for both the tone words (stimulus (1)) and the consonant words (stimulus (2)), but no ear advantage for hums (stimulus (3)). English listeners, regardless of musical training, showed a REA for the consonant words of stimulus (2) only. Taken together, these findings suggest that pitch perception is lateralized to the LH when pitch variations

signal language-specific functions. No ear advantage is observed for tone words in either the musically untrained or the musically trained English group, because pitch patterns are not exploited at the syllable level in English. It is unlikely that the REA for Thai tones can be attributed simply to greater familiarity with pitch contrasts, since the musically trained English group failed to show a right ear advantage for tone words. A right ear advantage for consonant words is observed in both Thai and English groups, because initial consonants are contrastive in both languages. The hums yielded no significant ear effects regardless of language experience, because they were not linguistically significant.

A left hemisphere superiority for dichotic perception of lexical tone has also been demonstrated in Mandarin Chinese (Wang *et al.*, 2001, and references therein). Stimuli consisted of four quadruplets of Mandarin words distinguished minimally by tone. Musically untrained English listeners served as the control group. A REA for the tone words was observed in the Mandarin group only. No ear advantage was found for the nontone language listeners. Dichotic perception of the two Norwegian pitch accents similarly reveals a LH advantage for Norwegian words differing only in tone. These findings combined reinforce the view that lateralization of pitch processing varies, depending on language experience. Hemispheric specialization appears to be based on language functions instead of physical parameters.

All of the aforementioned studies of dichotic perception of tone used real words as stimuli. Thus, it may be the case that these findings on prelexical processing of tone are confounded with lexical processing (Wong, 2002).

Lesion Deficits

Traditional models of language and the brain have presumed that certain functions are localized in specific areas of the brain. Most of this information has been drawn from studies of left-brain-damaged patients who have suffered strokes due to blockage of blood flow to the brain. Damage in specific areas may be responsible for specific language deficits, or aphasias (for review of aphasic syndromes, see Dronkers *et al.* (2000)). The LH is also dominant for language functions in native speakers of tone languages, as in nontone languages (Gandour, 1998a; Packard, 2005). All current information on tonal breakdown comes from aphasics who are native speakers of tone languages spoken in the Far East. No information is available in the extant literature on aphasics who are native speakers of tone languages in other parts of the world, especially Africa and Central America. The African and Central American languages are typologically different from those in Asia with respect to tonal inventories and rule systems, and represent a gap in our knowledge of the neurophonetics of tone.

Relevant to tonal processing, it is well known that the RH plays a critical role in pitch production and perception (Zatorre *et al.*, 2002). Since pitch is the primary auditory correlate of lexical tone, it is of theoretical interest to explore the nature of tonal breakdown after unilateral brain damage. If hemispheric specialization is driven primarily by acoustic cues regardless of function, then we expect to observe tonal disturbances subsequent to RH lesions. On the other hand, if hemispheric specialization is driven primarily by language function, then we expect to observe tonal deficits subsequent to LH lesions.

Production

Tones, like consonants and vowels, may be disrupted subsequent to LH damage (Baum and Pell, 1999; Gandour, 1987, 1998a; see Wong, 2002). The bulk of the research has focused on tonal production in isolated monosyllabic words (Mandarin Chinese, Cantonese, and Thai). Variability in the magnitude of tonal deficits appears to be related primarily to aphasia severity. The more severe the aphasic impairment, the more difficulty the patient experiences in producing tones. Although the extent of disruption varies in LH patients depending on severity level, tonal production appears not to be impaired following unilateral lesions to the RH. Pitch accent contrasts in Norwegian are also more perturbed in LH-damaged patients than in RH-damaged patients.

The magnitude of tonal disruption (or preservation) relative to consonants and vowels may serve as an index of segmental vs. suprasegmental autonomy in speech production. In Mandarin Chinese, both tones and consonants appear to be equally vulnerable in LH-damaged patients with nonfluent aphasia. Its tones, however, are observed to be more vulnerable to disruption than vowels are (Liang and Heuven, 2003). In Thai, tones produced by a Broca's aphasic are preserved, in contrast to a severe impairment in producing consonants. Sequences of phonemic approximations (SPAs) to a single target word on a picture-naming task may yield data crucially relevant to the issue of autonomous representations in speech planning (Gandour *et al.*, 1994). SPAs exhibit a general tendency of steady progression toward the target, which supports the notion that conduction aphasics suffer from a general deficit in phonological encoding. In the study by Gandour *et al.* (1994), in the

course of the participant's SPAs, tonal information was accessed earlier than was information for consonants or vowels. Within the participant's SPAs, tonal information was more stable than segmental across successive approximations. Such findings are compatible with the view that phonological information about a word is not accessed as an indivisible whole, but rather in parts, and, furthermore, that these parts or tiers become available in stages in generating the phonological plan of a word (see Liang and Heuven, 2003).

There is some evidence for selective deficits in the production of particular types of tonal contours. For example, the third tone in Mandarin Chinese, which exhibits a bidirectional, falling–rising contour, is especially vulnerable to disruption. In a study of tones produced by LH-damaged nonfluent patients, the third tone accounts for over half of the tonal confusions. However, in Cantonese, production errors by LH-damaged patients have been reported to be evenly distributed across the six tones, level and contour alike. In productions of citation forms of Thai tones by LH-damaged patients, almost all tonal substitutions result in a mid, low, or falling tone. Of the five Thai tones, the mid, low, and falling tones are characterized primarily by a falling F_0 trajectory throughout their duration, whereas the high and rising tones are not. These findings are compatible with the notion that tones exhibiting a falling F_0 contour are articulatorily less complex than others.

In a case study by Liang and Heuven (2004), the four Mandarin Chinese tones were not all equally vulnerable to disruption when produced in isolated monosyllabic words by a Broca's aphasia patient. Perceptual evaluation of the patient's tonal productions indicated that the high level tone was preserved, whereas the other three tones (high rising, low falling rising, and high falling) were severely impaired. This finding suggests that tones that exhibit dynamic F_0 contours are more difficult to produce than are those that do not. Moreover, the patient's vowels were spared relative to tones. Because vowels and tones are coterminous in production, these findings point to some degree of autonomy between segmental and suprasegmental aspects of speech production. The most salient characteristic across the four tones is their sharp, falling F_0 contour over the last 50% of their duration. The prevalence of falling contours has also been observed in a Thai Broca's aphasia patient (Figure 1). These findings are consistent with the notion that falling tones are easier to produce than rising tones are.

In nontone languages, aphasic speakers exhibit a narrowing of the F_0 range, especially in longer sentences. This inability to maintain a sufficiently wide

Figure 1 Average F_0 contours (Hz) of Thai tones normalized for time on a percent scale, as produced in isolated monosyllables by a normal adult (top) and by a patient with Broca's aphasia (bottom). In severe cases of aphasia in Thai-speaking patients, the only tone to be spared is the falling tone. Of the five Thai tones, it is the most resistant to disruption. Data adapted from Gandour J, Ponglorpisit S & Dardarananda R. (1992), 'Tonal disturbances in Thai after brain damage.' *Journal of Neurolinguistics 7*, 133–145, with permission.

F_0 range has been offered as an explanation for the prosodic disturbance, but this explanation cannot account for aphasic speakers of tone languages. For example, the opposite effect is seen in Thai aphasic speakers. Not only is there no compression of the F_0 range, but the tone space in LH-damaged patients actually reveals a wider than normal range. Therefore, it is unlikely that the difficulty aphasic speakers have in producing tonal contrasts, at least for tones in isolated words, can be attributed to a narrowing of the F_0 range.

Figure 2 The F_0 contours of a Thai sentence (*This would make him think that it was dark*) produced by a Thai-speaking Broca's (B) aphasia patient (top) and a normal adult speaker (bottom). The sequence of tones is mid, mid, falling, high, falling, falling, high. A dotted line is drawn through the fifth harmonic in the narrowband spectrograms (4-kHz frequency range; 75-Hz analysis filter). The speaking rate and rhythm of the Broca's aphasia patient were markedly impaired (she produced speech on a syllable-by-syllable basis). Deviant timing notwithstanding, she had no difficulty in producing Thai tones in connected speech. In comparison to the normal speaker, the patient's F_0 contours resemble more closely those that occur in isolated monosyllables. The effects of tonal coarticulation and sentence intonation are minimized in the patient's speech due to her inability to control F_0 over a temporal domain larger than a single syllable. Reprinted from Gandour J, Holasuit Petty S & Dardarananda R (1989). 'Dysprosody in Broca's aphasia: a case study.' *Brain and Language 37*, 232–257, with permission.

Rather than attribute the disruption of intonation contours in nontone languages to a malfunction in F_0 mechanisms, it seems more likely that F_0 disturbances in connected speech may be secondary to an underlying timing disorder. Indeed, a case study of a Thai Broca's aphasia patient clearly showed that F_0 contours of the five Thai tones were preserved in sentence-level discourse, despite the fact that the patient's timing was aberrant (Figure 2). Deviant timing at the sentence level necessarily disrupts F_0 contours associated with intonation, but not tone. This suggests that tonal contours may be less disrupted than intonation is because of the smaller temporal domain over which they extend.

To investigate production of tones at the intersyllabic level, tonal coarticulation was investigated in Thai aphasic patients (Gandour *et al.*, 1996). Coarticulation refers to the phenomenon whereby a given speech sound is altered in its phonetic manifestation, depending on influences from adjacent sounds. In tones, coarticulatory effects occur in much the same way as in consonants and vowels. Anticipatory and perseverative coarticulation, respectively, involve one speech sound being influenced by subsequent and preceding sounds. All 25 possible sequences of two tones from the set of five Thai tones were embedded in a carrier sentence. Anticipatory and perseverative tonal coarticulation were markedly reduced in left-fluent aphasic patients, were totally absent in left-nonfluent aphasic patients, but were reasonably well preserved in RH-damaged patients. The disparity in performance between LH- and RH-damaged patients supports the notion that tonal coarticulation is predominantly a LH function.

At the sentence level, the question arises whether lexical tones preserve their identity under the influence of intonation. A common phenomenon in most languages is a gradual lowering of F_0 during the course of an utterance, i.e., declination. A breakdown in intonation is expected, especially in nonfluent aphasic patients, because of the length of the utterances over which declination spans. To test the

interaction between tone and intonation, Thai sentences were constructed with three stressed keywords in sentence-initial, -medial, and -final positions (Gandour *et al.*, 1997). For both normal and brain-damaged speakers, results indicated that the average F_0 of tones in sentence-final position was significantly lower in F_0 than in either sentence-initial or -medial position. Contrary to expectation, no differences in task performance could be attributed to either the LH or RH. Perhaps Thai sentence intonation is manifested primarily as a final lowering effect, instead of declination. In this experiment, brain-damaged patients had to implement this lowering effect over only the small, final portion of the sentence. It is also well known that stressed syllables are less vulnerable to disruption than unstressed syllables are. The degree to which brain-damaged patients suffer prosodic deficits reflects, in part, an interaction between stress and utterance length.

Perception

Tonal breakdown in perception reveals that the LH is dominant for the perception of lexical tones in Mandarin Chinese, Cantonese, Thai, and Toisanese (Baum and Pell, 1999; Gandour, 1998a,b). Those tones that are most susceptible to perceptual confusion are precisely those that are phonetically similar in height and shape to others in the tone space. For example, the mid and low tones are vulnerable to confusion in Thai and the high rising (tone 2) and low falling rising (tone 3) tones are vulnerable to confusion in Mandarin Chinese. The LH also emerges as the dominant hemisphere for the perception of Norwegian pitch accent distinctions. Although some caution is in order due to methodological concerns (Wong, 2002), the extant data on tonal deficits clearly implicate the LH.

Functional Neuroimaging

Functional neuroimaging refers to methods that are currently available for the noninvasive measurement of brain activity in humans (for review of functional neuroimaging methods in cognitive neuroscience, see Rugg (1999)). The role neuroimaging plays in cognitive neuroscience is to allow identification of functional-level elementary operations that support cognitive processing (e.g., language) and determination of how these operations are instantiated in the human brain (Binder and Price, 2001). Modern functional brain imaging techniques include, among others, positron emission tomography (PET), functional magnetic resonance imaging (fMRI), and magnetoencephalography (MEG) (see Rugg, 1999, and references therein). These brain imaging methods complement the lesion-deficit approach. Most importantly, they provide a window for viewing neural activity underlying cognitive processing in both hemispheres *in vivo* in neurologically intact subjects. In regard to speech prosody, an overwhelming majority of the brain imaging experiments to date have focused on the underlying basis for hemispheric asymmetry in speech perception (Baum and Pell, 1999; Dogil *et al.*, 2002; Gandour, 2005; Wong, 2002).

Tone

In studies of pitch processing, a fundamental question is whether shared neural mechanisms at higher cortical levels are engaged for pitch perception of linguistic and nonlinguistic auditory stimuli. PET was used to compare pitch processing in native speakers of two tone languages, Chinese and Thai, and in speakers of English, a nontone language (Gandour *et al.*, 2000). Participants were asked to perform focused-attention, speeded-response, auditory discrimination judgments of tone and pitch vs. a passive silent baseline. In the tone condition, they judged pitch patterns of Thai tones; in the pitch condition, they judged homologous pitch patterns in nonspeech stimuli. When comparing the tone to the pitch task, only the Thai group showed significant activation in left posterior inferior frontal regions. These differential patterns of brain activation across language groups and tasks support the view that pitch patterns are processed at higher cortical levels in a top-down manner according to their linguistic function in a particular language.

A LH specialization for tonal processing is also observed in native speakers of Mandarin Chinese when they are asked to make discrimination judgments of Chinese tones and of homologous pitch patterns in low-pass-filtered versions of the same stimuli (Gandour, 2005, and references therein). Chinese listeners extracted tonal information associated with the Chinese tones via left inferior frontal regions in both speech and nonspeech stimuli (**Figure 3**). The tone task required judgments of Chinese pseudowords; the pitch task required judgments of nonwords. Chinese listeners apparently respond to tonal phonemes at the prelexical stage of processing in both tasks, as evidenced by the absence of any significant increases in regional blood flow on the tone task relative to pitch. Conversely, English listeners exhibited activation in homologous areas of the RH. Pitch processing is lateralized to the LH only when the pitch patterns are phonologically significant to the listener; otherwise, processing is lateralized to the RH. A similar leftward asymmetry was observed in the Chinese group when judging Chinese

Figure 3 Averaged positron emission tomography (PET) activation maps of Mandarin Chinese (left) and English (right) listeners for the tone (top panel) and pitch (bottom panel) tasks, superimposed on anatomic images transformed to a standard stereotaxic space (T, tone; P, pitch; F3o, inferior frontal gyrus/pars opercularis; PRG, precentral gyrus/premotor cortex; F3t, inferior frontal gyrus/pars triangularis; FO, frontal operculum; INS, insula; FP, frontal pole). Activation foci are observed in the left inferior frontal gyrus of Chinese listeners in both the tone and pitch tasks relative to passive listening. In the pitch task, activation patterns in the left and right frontal lobes are complementary between language groups. Data adapted from Hsieh L, Gandour J, Wong D & Hutchins G (2001). 'Functional heterogeneity of inferior frontal gyrus is shaped by linguistic experience.' *Brain and Language 76*, 227–252, with permission.

consonants and vowels. It appears that LH mechanisms mediate processing of linguistic information irrespective of acoustic cues or type of phonological unit, segmental or suprasegmental.

Whether a particular auditory/acoustic cue serves a phonological function in a listener's native language dictates laterality. No activation occurs in left frontal regions for English listeners on either the tone or pitch task because they judge auditory features of Chinese tones that are not phonologically significant in the English language. Similarly, when judging Thai tones, Chinese listeners fail to show activation of LH regions (Gandour *et al.*, 2000, 2002).

Tone vs. Vowel Length

Whereas some studies support speech-specific circuits, others suggest that lateralization is dictated by relative computational demands of complex auditory signals in the spectral or time domains. To examine how the brain processes linguistically relevant spectral and temporal information, fMRI was used to investigate Thai speech, a language in which spectral processing, associated with lexical tones, and temporal processing, associated with vowel length, can be differentiated (Gandour *et al.*, 2002). Thai and Chinese participants were asked to perform discrimination judgments of pitch and timing patterns presented in the same auditory stimuli in two different contexts: linguistic (Thai speech) and nonlinguistic (nonspeech hums). In the speech condition, tasks required judging Thai tones (T) and vowel length (VL); in the nonspeech condition, tasks required judging homologous pitch contours (P), and duration patterns (D). A remaining task required listening passively to nonspeech hums (L). Only the Thai group showed activation in the left inferior prefrontal cortex in speech minus nonspeech contrasts for spectral (T vs. P) and temporal (VL vs. D) cues (Figure 4). Thai and Chinese groups, however, exhibited similar frontoparietal activation patterns in nonspeech hums minus passive listening contrasts for spectral (P vs. L) and temporal (D vs. L) cues. Regardless of the neural mechanisms underlying low-level auditory processing, these findings clearly indicate that hemispheric specialization is sensitive to language-specific factors. The type of acoustic cue underlying a phonological contrast is not as important as whether a particular cue serves a phonological function. Like Thai, the Chinese language exploits variations in F_0 to signal tonal contrasts. Unlike Thai, temporal variations in vowels are not exploited phonologically. Despite experience with lexically contrastive F_0 contours, the Chinese group still failed to show LH lateralization for Thai tones.

Tone vs. Onset/Rhyme

The optimal test for phonetic extraction requires that nonminimal pairs (e.g., *beep* vs. *doom*) be compared directly to minimal pairs (e.g., *bag* vs. *gag*). In nonminimal pairs, subjects must separate the individual phonetic units from the whole syllable in order to make a same/different judgment. In minimal pairs, subjects do not necessarily need to tease apart the phonetic units or even to be able to classify the paired stimuli into linguistic categories. A crosslinguistic fMRI study (Gandour, 2005) was conducted to investigate neural mechanisms involved in extraction of Chinese consonants (onsets), rhymes, and tones from minimal and nonminimal pairs. Chinese and English subjects performed discrimination judgments of targeted subsyllabic units. Direct between-group comparisons of consonants, rhymes, and tones in both minimal and nonminimal pairs, segmental and suprasegmental alike, revealed increased activation

Figure 4 Averaged functional magnetic resonance imaging (fMRI) activation maps for the groups of native Thai and Chinese speakers, showing crosslinguistic differences in brain activation for the spectral contrast between Thai tones (T) and pitch (P) (top panel) and the temporal contrast between Thai vowel length (VL) and duration (D) (bottom panel). Each panel shows a left sagittal section through stereotaxic space of activation maps, superimposed onto a representative brain anatomy. Left-sided activation foci in frontal and temporo-occipital regions occur in the Thai group only. Student's *t*-statistic values are represented by a color scheme whereby the significance levels increase from red to yellow. Reprinted from Gandour J, Wong D, Lowe M, Dzemidzic M, Satthamnuwong N, Tong Y, *et al.* (2002). 'A cross-linguistic FMRI study of spectral and temporal cues underlying phonological processing.' *Journal of Cognitive Neuroscience 14*(*7*), 1076–1087.

for the Chinese group in a widely distributed network in frontal, parietal, and temporal regions of the LH. Within-group comparisons of nonminimal and minimal pairs showed that frontal and parietal activity varies for each subsyllabic component. In the frontal lobe, for example, the Chinese group showed bilateral activation of the anterior middle frontal gyrus (MFG) for rhymes and tones only. Rhymes induced greater activation in the left posterior MFG for the Chinese group when compared to consonants and tones in nonminimal pairs (Figure 5). The activation of this network in processing nonminimal pairs shows that phonetic segmentation varies as a function of the subsyllabic unit in relation to both task demands (e.g., attention, memory) and syllable structure. The fact that the rhyme elicits greater activation in the left posterior MFG than either consonant or tone does indicates that not all units are treated alike in terms of phonetic segmentation.

Tone vs. Syllable

In an attempt to isolate mediational components that may be involved in phonetic extraction, an fMRI experiment was conducted on Mandarin Chinese tones to compare tonal matching to a control condition in which whole syllables are matched to one another (Gandour, 2005). In both conditions, auditory stimuli and task procedures were kept constant. It is thus possible to segregate the extraction of subsyllabic units from whole syllables, mediated by selective attention, which is guided either to a subpart of the syllable or to the whole syllable. Results showed a left-sided frontoparietal attention network, including a dorsolateral region of posterior prefrontal cortex in the vicinity of the junction of the precentral and inferior frontal sulci (PCS/IFS), a medial frontal presupplementary motor area (pre-SMA), and regions within the superior parietal lobule (SPL) (Figure 6). This network, in full or in part, has been observed in other studies that cut across sensory modalities, linguistic categories, and other domains. The pre-SMA retrieves a memory scheme for initiating preparation prior to each processing step in the task; the PCS/IFS junction area encodes the perceived signal, stores it for immediate matching, and transfers the matched code to the neighboring motor area for a response; the SPL marks and maintains the engagement of the activity in the PCS/IFS area so that the to-be-matched target and probe can be properly paired. In the language domain, these mediational processes make it possible for a listener to extract linguistically significant parameters in his/her native language.

Tone vs. Intonation

Speech prosody is processed in neither a single region nor in a specific hemisphere, but engages multiple areas comprising a large-scale spatially distributed network in both hemispheres. Evidence supporting a RH role in the perception of prosodic units at phrase- and sentence-level structures has been wide-ranging (Baum and Pell, 1999). Equally compelling has been evidence supporting involvement of the LH in the perception of prosodic units at syllable- or word-level structures. A key question is whether the observed laterality effects in tone perception are due to level of linguistic representation or to size of temporal domain, or to both. Chinese tones are manifested at the syllable level and intonation is manifested at the sentence level. When asked to compare lexical tones in three-syllable sentence pairs, Chinese listeners show frontoparietal activation in the LH (Gandour, 2005). Bilateral frontoparietal activity is observed when they are asked to compare intonation in the same sentences. In a direct comparison of tone and

Figure 5 Averaged functional magnetic resonance imaging (fMRI) activation maps obtained from comparison of consonant vs. rhyme vs. tone tasks by nonminimal and minimal pair conditions within the Chinese (upper panel) and English (lower panel) language groups (C, consonant; R, rhyme; T, tone; L, left hemisphere; R, right hemisphere). The Chinese group shows a common focus of activation in the left posterior middle frontal gyrus in comparisons of $R_{nonminimal}$ minus $C_{nonminimal}$, $R_{nonminimal}$ minus $T_{nonminimal}$, and $R_{minimal}$ minus $T_{minimal}$. The English group, on the other hand, shows activation of the posterior middle frontal gyrus and inferior parietal lobule bilaterally in comparisons of $T_{nonminimal}$ minus $C_{nonminimal}$ and $T_{nonminimal}$ minus $R_{nonminimal}$. Reprinted from Gandour J, Xu Y, Wong D, Dzemidzic M, Lowe M, Li X, *et al.* (2003). 'Neural correlates of segmental and tonal information in speech perception.' *Human Brain Mapping 20*(*4*), 185–200.

intonation, the latter is found to engage only RH mechanisms in frontotemporal regions.

In an fMRI study (Gandour *et al.*, 2004), brain activity was elicited by selective attention to Chinese intonation and tone presented in three-syllable and one-syllable sentence pairs. The Chinese group exhibited greater activity than the English group did in a left inferior parietal region, across tasks. Only the Chinese group exhibited a leftward asymmetry in inferior parietal and posterior superior temporal, anterior temporal, and frontopolar regions. Both language groups shared a rightward asymmetry in the midportions of the superior temporal sulcus and MFG, irrespective of prosodic unit or temporal interval.

These crosslanguage differences in laterality of particular brain regions are hypothesized to depend on a listener's implicit knowledge of the relation between external stimulus features (acoustic/auditory) and internal conceptual representations (linguistic/prosodic). All regions in the frontal, temporal, and parietal lobes that are lateralized to the LH in response to all tasks or subsets of tasks are found in the Chinese group only (Figure 7). Conversely, the two regions in the temporal and frontal lobes that are lateralized to the RH are found in both language groups. LH laterality reflects higher order processing of internal representations of Chinese tone and intonation, whereas RH laterality reflects lower order processing of complex auditory stimuli (see Valaki *et al.*, 2004). These findings cannot be explained by a model that claims that segmental, lexical (e.g., tone), and syntactic information is processed in the LH and that suprasegmental sentence-level information (e.g., intonation) is processed in the RH (Friederici and Alter, 2004). Rather, they most likely reflect task demands related to retrieval of internal representations associated with tone and intonation.

Tone Perception by Nonnative Speakers

Evidence from the behavioral, neuropsychological, and functional neuroimaging literature consistently points to the lack of LH dominance in the processing of lexical tone by English speakers who have had no prior experience with a tone language. The question arises as to what the effects on brain processing are for nonnative speakers learning a tone-based second language (L2). Cortical modification resulting from L2 acquisition of Mandarin Chinese tones was investigated using fMRI to compare cortical activation

Figure 6 Averaged functional magnetic resonance imaging (fMRI) activation map obtained from a direct comparison of tone vs. syllable discrimination judgments for a group of 12 native speakers of Chinese (IFS, inferior frontal sulcus; SMA, supplementary motor area; SPL, superior parietal lobule). This horizontal section shows brain activity in dorsal aspects of the left frontal and parietal lobes. Data adapted from Li X, Gandour J, Talavage T, Wong D, Dzemidzic M, Lowe M, *et al.* (2003). 'Selective attention to lexical tones recruits left dorsal frontoparietal network.' *NeuroReport 14*(*17*), 2263–2266.

Figure 7 Laterality effects for regions of interest (ROIs) in the Chinese group only, and in both Chinese and English groups, rendered on a three-dimensional left hemisphere (LH) template for common reference. In the Chinese group (top panel), the inferior parietal lobule (IPL), anterior superior temporal gyrus (aSTG), and posterior superior temporal gyrus (pSTG) are left-lateralized (LH > RH) across tasks; the anterior middle frontal gyrus (aMFG) (I1, I3) and inferior parietal sulcus (IPS) (T3) are left-lateralized for specific tasks. In both groups (bottom panel), the mid middle frontal gyrus (mMFG) and mid superior temporal sulcus (mSTS) are right-lateralized (RH > LH) across tasks (bottom right panel). Other ROIs do not show laterality effects. No region of interest elicited either a rightward asymmetry for the Chinese group only, or a leftward asymmetry for both Chinese and English groups. Reprinted from Gandour J, Tong Y, Wong D, Talavage T, Dzemidzic M, Xu Y, *et al.* (2004). 'Hemispheric roles in the perception of speech prosody.' *Neuroimage 23*, 344–357, with permission.

during a tone identification task before and after a 2-week training procedure for adult English-speaking beginning learners (for review of Mandarin Chinese tone processing by second-language learners, see Wang *et al.* (2005)). Cortical effects of learning Chinese tones were associated with increased activation in the left posterior superior temporal gyrus (STG), recruitment of additional cortical volume within adjacent regions of the left STG, and recruitment of additional cortical volume within the right inferior frontal gyrus. These early cortical effects of learning lexical tones involve both the expansion of preexisting language-related areas and the recruitment of additional cortical regions specialized for functions required by the second language.

Conclusions

Lexical tones are better thought of as emerging from a mosaic of multiple local asymmetries, whereby different regions are differentially weighted in laterality, depending on cognitive domain, sensory modality, and task-related features. Hypotheses that are function-based or parameter-based capture only part of the phenomenon (see Dogil *et al.* (2002) and Friederici and Alter (2004); for competing hypotheses on speech prosody and the brain, see Ivry and Robertson (1998) and Zatorre *et al.* (2002)). The view here is that lexical tones, or intonation, for that matter, are lateralized to neither the LH nor the RH exclusively (Gandour *et al.*, 2004).

A viable, neurobiological model of speech prosody must allow for dynamic interactions between the two

hemispheres via the corpus callosum. Whereas the RH is engaged in pitch processing of complex auditory signals, including pitch variations associated with various aspects of speech prosody, the LH appears to be recruited to process categorical information to support phonological processing, as well as syntactic and semantic processing (see Friederici and Alter, 2004). Neuroimaging data point to functional segregation of frontal, temporal, and parietal regions, as well as to their functional integration as part of widely distributed cortical networks (for conceptual frameworks that have been proposed to underlie the neuroanatomical and functional organization of speech perception, see Hickok and Poeppel (2004) and Scott and Wise (2004)). For example, LH networks in the temporal lobe that are sensitive to phonologically relevant parameters from the auditory signal are located in anterior and posterior, as opposed to central, regions of the STG/STS (Gandour *et al.*, 2004). The anterior region appears to be part of an auditory–semantic processing stream and the posterior region appears to be part of an auditory–motor processing stream. Both processing streams, in turn, project to convergence areas in the frontal lobe. Such perspectives are essential for future advances in our understanding of the neural bases of speech prosody.

Tone: Phonology

M Yip, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A tone language is a language in which the pitch of the voice can change the meaning of the word. In Cantonese (Chinese, Yue), for example, [yau] has six meanings depending on its tone:

(1) *[yau] in Cantonese*

high level	'worry'	high rising	'paint' (N)
mid level	'thin'	low level	'again'
very low level	'oil'	low rising	'have'

This is distinct from intonation, in which pitch changes may signal sentence-level meanings such as questions or surprise. All languages seem to use pitch intonationally, but only some 60–70% are like Cantonese in using it lexically. This includes most of the languages of sub-Saharan Africa, east and southeast Asia, and Central America; many in North and South America and the Pacific; and even a number of languages of Western Europe, such as Swedish and some varieties of Dutch. The only continent which seems to have no tone languages is Australia.

Tone languages may distinguish at least four different pitch levels, as in the West African language Mambila and the Mexican language Mazateco, and some contrast five levels, such as Dan (West Africa), Miao-Yao (Southeast Asia), and Trique (Mexico). They may also distinguish between level tones, rising tones, falling tones, and more complex rise-falls or fall-rises. Cantonese, for example, has four levels (one of which falls slightly) and two rises. Two contours of the same shape seem to be the maximum, although there are rare reports of three, for example Chatino (Mexico).

Pitch is controlled by the larynx in ways that are not fully understood, but that include varying the tension of the vocal folds and the height of the larynx. These laryngeal mechanisms also play a role in voicing, glottalization, and aspiration, and this fact underlies the historical origins of tone. Typically, a contrast between voiced and voiceless syllable-initial consonants gave rise to a contrast between lower and higher tones on the following vowel. Glottal stops and [h] at the end of the syllable gave rise to rising and falling tones respectively on the preceding vowel. This process is known as tonogenesis, and is well documented and understood, particularly in the languages of east and southeast Asia. See Hombert *et al.* (1979) for an excellent review.

The main acoustic correlate of tone is the fundamental frequency of the speech signal, known as $F_{Ø}$. This is the rate of vibration of the vocal folds, and ranges from a low of around 80 cycles per second for the lowest speaking pitch of a male voice, to a high of around 400 cycles per second for the highest speaking pitch of a female voice. As a result, the high tone of male may have an $F_{Ø}$ that is lower than the low tone of a female or a child.

The actual pitch of a tone may depend on its context. A striking example is the phenomenon known as 'downstep.' In many languages with a high (H) vs. low (L) tone contrast, high tones are pronounced lower in pitch after a low tone than they are after another high. This gives the illusion of a third tone with a mid pitch, but it is entirely predictable from the context. The process repeats, so each subsequent

A tone language is a language in which the pitch of the voice can change the meaning of the word. In Cantonese (Chinese, Yue), for example, [yau] has six meanings depending on its tone:

(1) *[yau] in Cantonese*

high level	'worry'	high rising	'paint' (N)
mid level	'thin'	low level	'again'
very low level	'oil'	low rising	'have'

This is distinct from intonation, in which pitch changes may signal sentence-level meanings such as questions or surprise. All languages seem to use pitch intonationally, but only some 60–70% are like Cantonese in using it lexically. This includes most of the languages of sub-Saharan Africa, east and southeast Asia, and Central America; many in North and South America and the Pacific; and even a number of languages of Western Europe, such as Swedish and some varieties of Dutch. The only continent which seems to have no tone languages is Australia.

Tone languages may distinguish at least four different pitch levels, as in the West African language Mambila and the Mexican language Mazateco, and some contrast five levels, such as Dan (West Africa), Miao-Yao (Southeast Asia), and Trique (Mexico). They may also distinguish between level tones, rising tones, falling tones, and more complex rise-falls or fall-rises. Cantonese, for example, has four levels (one of which falls slightly) and two rises. Two contours of the same shape seem to be the maximum, although there are rare reports of three, for example Chatino (Mexico).

Pitch is controlled by the larynx in ways that are not fully understood, but that include varying the tension of the vocal folds and the height of the larynx. These laryngeal mechanisms also play a role in voicing, glottalization, and aspiration, and this fact underlies the historical origins of tone. Typically, a contrast between voiced and voiceless syllable-initial consonants gave rise to a contrast between lower and higher tones on the following vowel. Glottal stops and [h] at the end of the syllable gave rise to rising and falling tones respectively on the preceding vowel. This process is known as tonogenesis, and is well documented and understood, particularly in the languages of east and southeast Asia. See Hombert *et al.* (1979) for an excellent review.

The main acoustic correlate of tone is the fundamental frequency of the speech signal, known as $F_{Ø}$. This is the rate of vibration of the vocal folds, and ranges from a low of around 80 cycles per second for the lowest speaking pitch of a male voice, to a high of around 400 cycles per second for the highest speaking pitch of a female voice. As a result, the high tone of male may have an $F_{Ø}$ that is lower than the low tone of a female or a child.

The actual pitch of a tone may depend on its context. A striking example is the phenomenon known as 'downstep.' In many languages with a high (H) vs. low (L) tone contrast, high tones are pronounced lower in pitch after a low tone than they are after another high. This gives the illusion of a third tone with a mid pitch, but it is entirely predictable from the context. The process repeats, so each subsequent

H after a L is lower still. In Shona, a Bantu language, an underlying LHLHLHLH sequence is pronounced with each H lower than the last.

Phonologists working on tone have made two striking claims. First, contour tones are not indivisible units characterized by features such as [+rising] or [+falling], but instead are composed of sequences of level tones. A rise is a LH sequence, and a fall is a HL sequence, pronounced on a single syllable. Second, tones have a high degree of independence from the segments on which they are pronounced, very much like the melody of a song is separate from the lyrics. As a result they show a number of unusual behaviors: mobility, stability, one-to-many mapping, many-to-one mapping, toneless syllables, and floating tones.

Mobility is the ability of a tone to move a long distance from its point of origin. For example, in the Bantu language Chizigula (Kenstowicz and Kisseberth, 1990) some verbs such as /lo̱mbez/ have underlying H tones, shown by the underlined syllable, and every form of the verb is pronounced with one high-toned syllable. However, the tone does not necessarily show up on the verb root, but instead on the penultimate syllable of the suffixed verb, as can be seen in the right-hand column below. In contrast, the left-hand column shows a verb with no high tone, in which no syllable has high surface pitch. Here and henceforth, an acute accent denotes H tone, and a grave accent or no accent L tone.

(2)	*Toneless verbs:*		*H-tone verbs:*	
	ku-damany-a	'to do'	ku-lo̱mbéz-a	'to request'
	ku-damany-iz-a	'to do for'	ku-lo̱mbez-éz-a	'to request for'
	ku-damany-iz-an-a	'to do for e.o.'	ku lo̱mbez-ez-án-a	'to request for e.o.'

Stability is the resistance of tones to deletion or movement, even when the vowels on which they originate are deleted or moved. In Thai, a language game exchanges portions of two syllables. However, the tones stay behind, so that the tonal melody is unaffected. In the example below, the /H/ from /en/ stays behind on the first syllable, and surfaces on [am]. /en/ on the other hand surfaces with the /M/ that originated on /am/. A horizontal macron shows mid tone.

(3) tén rām → tám rēn 'dance' (Melody: H M)

One-to-many and many-to-one refer to the mappings between tones and syllables. In a one-to-many mapping, one tone spreads out over several syllables to form a tonal plateau. In Chiquihuitla Mazatec (Mexico; Jamieson, 1977) we see unbounded spread of high tones. In this example, the last tone of the first morpheme spreads rightwards, obliterating all other tones except the last:

(4) kihMH -nkaM -muMsuML → kihMH nkaH muHsuHL
went again hired worker

In a many-to-one mapping, two or more tones are pronounced on single syllable. In Siane nouns (Papua New Guinea; James, 1994), contours are formed only when excess tones have nowhere else to go. A monosyllabic noun with two underlying tones LH shows up with only the L tone on the noun root, and the H tone on any suffix. Only if there is no suffix do the two tones surface on the noun itself, forming a rising contour shown by the hacek accent.

(5)	/yoLH/	yo + te	→	yòLtéH	'fire, 1sg.poss'
		yo	→	yǒLH	'fire'

Finally, even in tone languages, some syllables may be underlyingly toneless, and take their phonetic pitch entirely from the surrounding tones. This is also a common outcome for unstressed syllables which may lose any underlying tones. Conversely, some tones may not have underlying segmental hosts. These 'floating tones' manifest their presence only when they attach to a neighboring tone. In Cantonese, for example, there is a suffix that consists solely of a H tone (Yip, 2002). When this attaches to the final syllable of a word, it creates a new tone that starts at the starting pitch of the original syllable, and ends high. Thus the low-toned /yipL/ becomes rising [LH], but the originally high falling /paiHL/ becomes high level [HH], squeezing out the L of the original fall. Such floating tones may exert influence on other tones even when they are not themselves pronounced. In many Bantu languages, floating L tones may cause 'non-automatic' downstep of a following H.

These properties of tone have given rise to a theory known as 'autosegmental phonology' (Goldsmith, 1976), in which tone is represented on a separate tier from the segments and linked to them by association lines. Under this approach, the two diagrams below show first a tonal plateau like the one created by spreading H tone in Mazateco above, and then a contour tone like the one created in Cantonese affixation:

(6) *Tonal plateau* *Contour tone*

The richness of these tonal patterns is constrained in a variety of ways. Contour tones, particularly rises, are often found only on final syllables or long vowels. High tones may be attracted to prominent or stressed positions. Languages may avoid sequences of two syllables with identical tones, so that two adjacent H-toned morphemes may dissimilate, with one becoming L or deleting. In Bantu, this well-known

process is called Meeussen's Rule, but it is understood as an instance of a very general phonological phenomenon applicable well beyond tonal phonology, dubbed the Obligatory Contour Principle, or OCP (Leben, 1973).

Although lexical tone may distinguish one word from another, it is also used for grammatical purposes. In many Bantu languages it signals tense and aspect distinctions, so that in the N. Karanga dialect of Shona (Odden, 1981) [..biki-is-a] means '*make cook*' but [..bik-ī́s-a], with a H tone on the second syllable, means '*didn't make cook*'. Tonal morphemes are common. In Yoruba (Akinlabi and Lieberman, 2000), subject noun phrases are marked by a H tone suffix, as in the first word in these sentences:

(7) L + H → LH bàtà já → bàtǎ já 'The shoe got cut'

(8) H + H → H Délé lɔ → Délé lɔ 'Dele went'

Tone interacts with the morpho syntax in other ways. Tones may change in a context that is partly defined by the syntax. In the Min dialects of Chinese (Chen, 2000), every tone has two variants. One is found phrase-finally, and the other is found elsewhere. The phrasing is determined largely by the syntax. The tonal changes are unusual, in that each tone changes to another one, creating a circular chainshift.

(9) *Taiwanese tonal changes: Min tone circle*

Although the summary so far may make tone seem very different from other properties of sounds, this is misleading. Many of the behaviors first noticed in tone have their counterparts in other areas of phonology. Tonal spreading has its analogues in vowel harmony and nasal harmony. Stability of tones under deletion has an analogue in the retention of nasality on a neighboring vowel after loss of a coda nasal. Contour tones, in some ways, resemble affricate consonants, in that both change a feature (tone or continuancy) midway through a segment. Loss of tones on unstressed syllables looks very similar to the reduction of unstressed vowels to schwa.

Can one discern subtypes of tonal systems as one looks across languages, and do these coincide with particular language families or geographical areas? Up to a point, the answer is 'yes,' but more careful scrutiny shows that 'Asian-type' tone languages are found in Africa, and vice versa. Further, the differences are more illusory than real. Traditionally, we think of African tonal languages as having (1) small tonal inventories, often just H versus L (2) few contour tones, and only on final syllables (3) very mobile tones (4) few tones per word. Asian tone languages, on the other hand, are usually said to have (1) large tonal inventories, with several levels and various contours (2) contour tones occurring prolifically and freely on any syllable (3) tones largely remaining in their underlying position (4) lots of tones per word. All of these generalizations turn out to have copious exceptions. For example, the West African Kru language Grebo (Liberian Grebo) (Newman, 1986) has four level tones and two different rising tones, and the rising tones are not restricted to final position. Conversely, Lhasa Tibetan, under some assumptions, (Duanmu, 1992), has only a H and a LH tone, and the LH only surfaces as a rise on final syllables. Elsewhere, the H moves off its original syllable onto the next syllable, exactly as in the African language Mende, or the New Guinea language Siane. Duanmu (2000) pointed out that many of the differences in tonal behavior follow from other facts about the languages in question. If a language has no heavy syllables, then it is less likely to have contour tones. Bantu languages, for example, often have a strict CV syllable structure, whereas Mandarin Chinese has CVV and CVC syllables. If a language has a rich affixing morphology, as in Bantu, then tones are likely to be more mobile; however, Chinese languages have few affixes, preferring to form new words through compounding.

One subtype of tonal languages is an accentual language, like Japanese or Lithuanian. Many phonologists would now argue that accent is represented as tone, but tone that is linked to a particular syllable and does not move around. Such languages have small tonal inventories (often only one) and each word has few tones (again, usually only one) (*see* **Accent**).

Tonga: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Tonga, also known as the Friendly Islands, is an archipelago of more than 150 volcanic and coral islands in the Southwest Pacific. Archaeological evidence shows that the first settlers in Tonga sailed from the Santa Cruz Islands, as part of the original Austronesian-speakers' migration that originated out of Southeast Asia some 6 000 years ago. By the 12th century, Tongans, and the Tongan paramount chief, the Tu'i Tonga, were known across the Pacific, from Niue to Tikopia, sparking some historians to refer to a Tongan Empire. A network of interacting navigators, chiefs, and adventurers might be a better term. In the 15th century and again in the 17th, civil war erupted. It was in this context that the first Europeans arrived, beginning with Dutch explorers Willem Schouten and Jacob Le Maire in 1616, but most significantly including Captain Cook in 1773, 1774, and 1777, the first London missionaries in 1797, and the Wesleyan Methodist Walter Lawrey in 1822. Tonga was united into a Polynesian kingdom in 1845 by the ambitious young warrior, strategist, and orator Taufa'ahau. He held the chiefly title of Tu'i Kanokupolu, but was baptized with the name King George. In 1875, with the help of missionary Shirley Baker, he declared

Tonga: Language Situation

Editorial Team

Tonga, also known as the Friendly Islands, is an archipelago of more than 150 volcanic and coral islands in the Southwest Pacific. Archaeological evidence shows that the first settlers in Tonga sailed from the Santa Cruz Islands, as part of the original Austronesian-speakers' migration that originated out of Southeast Asia some 6 000 years ago. By the 12th century, Tongans, and the Tongan paramount chief, the Tu'i Tonga, were known across the Pacific, from Niue to Tikopia, sparking some historians to refer to a Tongan Empire. A network of interacting navigators, chiefs, and adventurers might be a better term. In the 15th century and again in the 17th, civil war erupted. It was in this context that the first Europeans arrived, beginning with Dutch explorers Willem Schouten and Jacob Le Maire in 1616, but most significantly including Captain Cook in 1773, 1774, and 1777, the first London missionaries in 1797, and the Wesleyan Methodist Walter Lawrey in 1822. Tonga was united into a Polynesian kingdom in 1845 by the ambitious young warrior, strategist, and orator Taufa'ahau. He held the chiefly title of Tu'i Kanokupolu, but was baptized with the name King George. In 1875, with the help of missionary Shirley Baker, he declared

Tonga a constitutional monarchy, at which time he emancipated the serfs, he promulgated a new code of law, and limited the power of the chiefs. Tonga became a British protected state under a Treaty of Friendship in 1900, when European settlers and rival Tongan chiefs tried to oust the second king. The Treaty of Friendship and protected state status ended in 1970 under arrangements established prior to her death by the third monarch, Queen Salote. Tonga joined the Commonwealth of Nations in 1970 and the United Nations in 1999. The official languages of the Kingdom of Tonga are English and Tongan. The latter is a Polynesian language closely related to Niue. There are slight dialect differences from north to south. The ethnic group is predominantly monolingual in Tongan. A minority of islanders speak Niuafo'ou, which is probably a dialect of East Uvean (Wallisian). Most Niuafo'ou speakers are bilingual in Tongan. Another language, now extinct, is known from a few words collected by Westerners in the 17th century to have been in use on Tonga; Niuatoputapu disappeared before the 19th century and the ethnic group now speaks Tongan.

Tooke, John Horne (1736–1812)

P C Sutcliffe, Colgate University, Hamilton, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Tooke, born *John Horne* on June 25, 1736 in Westminster, was a cleric, political agitator and amateur philologist famous for writing *The diversions of Purley*, published in two volumes in 1786 and 1805. To honor his friend and patron, William Tooke, Horne added the name Tooke to his own in 1782, and he included Purley, Tooke's estate where Horne lived free of charge while writing the first volume of this large work, in its title. Horne Tooke was ordained in 1760, but his true interests lay in politics and the law. He was active in several organizations seeking constitutional reform, even founding the Constitutional Society around 1770. Such involvement landed him in prison in 1778, convicted of seditious libel for supporting the American colonists, and got him accused of treason in 1794, though he was acquitted. He eventually retired to Wimbledon where he died on March 18, 1812.

Tooke's imprisonment in 1778 first afforded him time to pursue a long-standing interest in language. He wrote *A letter to John Dunning, Esq.*, a 72-page linguistic analysis of the precedent that had been quoted against him, focusing particularly on the semantics and grammar of conjunctions and prepositions. He claimed to be the victim of "two prepositions and a conjunction."

This letter was later incorporated into the much longer *Epea pteroenta* or *The diversions of Purley*, which was written in the form of conversations involving himself, William Tooke, and Richard Beadon (Vol. 1) and himself and Sir Francis Burdett (Vol. 2). A third volume was planned for which Tooke even received some payments, but he burned it before his death.

The Greek title, *Epea pteroenta* ('winged words'), relates to the central notion of abbreviation in Tooke's theory of language. Starting with Locke's materialist philosophy (*see* **Locke, John (1632–1704)**), Tooke held that all ideas (and words) originally come from simple sensations, but complex ideas arise when one word is used to represent a series of sensations, and such words are 'abbreviations,' which are necessary to enable efficient communication. Tooke then used etymologies to reveal the 'true' meanings of words, the sensations from which they were derived (e.g., 'through' comes from 'door'). This was opposed to the grammars of Harris and Monboddo (*see* **Harris, James (1709–1780)** and **Burnett, James, Monboddo, Lord (1714–1799)**).

Tooke's political and linguistic ideas worked together. *The diversions of Purley* was essentially an attempt to undermine the idea that certain realms of discourse, such as politics and law, were only accessible to upper classes by showing the simple roots of ideas in experiences and etymologies that are universally accessible.

The impact of Tooke's *The diversions of Purley* was profound, influencing Coleridge and James Mill, among others, but it was quickly outmoded, though only reluctantly discarded in the English popular imagination, by developments in comparative philology in Germany.

Definitional Problems and History of the Terms

There are few terms and concepts in linguistics as problematic as Topic and Comment; few have had such a wide range of different applications that affect such fields as grammar, typology, pragmatics, and sociolinguistics. Moreover, few terms and concepts are relevant in so many different areas of application, from language instruction to professional writing (journalistic, official, legal, and political language) and from automatic text analysis to artificial intelligence. In fact, this pair of terms covers a wide range of far-reaching phenomena and properties that are found at the very center of the functioning of the linguistic system, such as referentiality, predication, the utterance-act, and information structure. The fact that definitions (and applications) were developed in different scientific spheres means that they have focused to a varying degree on these different aspects, which has at times prevented a clear view of all the problems and all the results. In addition, the general phenomena referred to above belong not only to a primarily philosophical but also to an empirical dimension, and we are still uncertain how we can reconcile these different dimensions; it is difficult to give definitive answers using individual models.

Although there are points of convergence and a level of continuity among the definitions, differences remain because their origins lie in different traditions, and the concepts have been adapted by changing scientific and cultural contexts. Attempting to superimpose terms belonging to different fields and periods is therefore problematic. The definition of Topic as 'what is being talked about' and Comment as 'what is being said about what is being talked about,' which is characteristic of American Structuralism (see Sapir, 1921; Hockett, 1958), is based on the axiom that these two parts are present in every declarative utterance. This is expressed in regulative terms by Lambrecht (1987: 254): "Do not introduce a referent and talk about it at the same time." He affirmed that the relation Topic-of "expresses the pragmatic relation of aboutness that holds between a referent and a proposition with respect to a particular discourse" (Lambrecht, 1994: 127). For an element to be able to assume the Topic function, it has to be referential. Moreover, the relation 'Topic of' is defined in entirely semantic terms: "A referent is interpreted as a topic of a proposition if in a given discourse the proposition is construed as being about this referent, i.e. as expressing information which is relevant to and which increases the addressee's knowledge of the referent" (Lambrecht, 1994: 127 and 131).

This type of definition and the axiom referred to above have their origins in a philosophical tradition that includes the whole history of Western thought. Although terms found in classical thought require accurate philological investigation and are not easily paired up with modern terms, one can argue that the splitting of an expression (*logos*) into "two inseparable semantic and referential functions" – *onoma* and *rhema* – was established by Plato and then taken up again by Aristotle (see Lyons, 1968; Lallot, 1988; Spina, 2002). Furthermore, linking referentiality to the utterance-act has an ancient provenance. The *onoma* signals actors and experiencers, whereas the *rheme* signals actions and events. Sometimes, the *onoma* is represented as content, and the *rheme* is represented as typically having an enunciative function (Spina, 2002; for an overview of the whole tradition, see Sandmann, 1979).

An underlying opposition has also been suggested for the notions of Theme and Rheme, as is found in European functional linguistics and text linguistics (*see* **Halliday, Michael A. K. (b. 1925)**; **Prague School**). In these fields, the pair is defined according

Definitional Problems and History of the Terms

There are few terms and concepts in linguistics as problematic as Topic and Comment; few have had such a wide range of different applications that affect such fields as grammar, typology, pragmatics, and sociolinguistics. Moreover, few terms and concepts are relevant in so many different areas of application, from language instruction to professional writing (journalistic, official, legal, and political language) and from automatic text analysis to artificial intelligence. In fact, this pair of terms covers a wide range of far-reaching phenomena and properties that are found at the very center of the functioning of the linguistic system, such as referentiality, predication, the utterance-act, and information structure. The fact that definitions (and applications) were developed in different scientific spheres means that they have focused to a varying degree on these different aspects, which has at times prevented a clear view of all the problems and all the results. In addition, the general phenomena referred to above belong not only to a primarily philosophical but also to an empirical dimension, and we are still uncertain how we can reconcile these different dimensions; it is difficult to give definitive answers using individual models.

Although there are points of convergence and a level of continuity among the definitions, differences remain because their origins lie in different traditions, and the concepts have been adapted by changing scientific and cultural contexts. Attempting to superimpose terms belonging to different fields and periods is therefore problematic. The definition of Topic as 'what is being talked about' and Comment as 'what is being said about what is being talked about,' which is characteristic of American Structuralism (see Sapir, 1921; Hockett, 1958), is based on the axiom that these two parts are present in every declarative utterance. This is expressed in regulative terms by Lambrecht (1987: 254): "Do not introduce a referent and talk about it at the same time." He affirmed that the relation Topic-of "expresses the pragmatic relation of aboutness that holds between a referent and a proposition with respect to a particular discourse" (Lambrecht, 1994: 127). For an element to be able to assume the Topic function, it has to be referential. Moreover, the relation 'Topic of' is defined in entirely semantic terms: "A referent is interpreted as a topic of a proposition if in a given discourse the proposition is construed as being about this referent, i.e. as expressing information which is relevant to and which increases the addressee's knowledge of the referent" (Lambrecht, 1994: 127 and 131).

This type of definition and the axiom referred to above have their origins in a philosophical tradition that includes the whole history of Western thought. Although terms found in classical thought require accurate philological investigation and are not easily paired up with modern terms, one can argue that the splitting of an expression (*logos*) into "two inseparable semantic and referential functions" – *onoma* and *rhema* – was established by Plato and then taken up again by Aristotle (see Lyons, 1968; Lallot, 1988; Spina, 2002). Furthermore, linking referentiality to the utterance-act has an ancient provenance. The *onoma* signals actors and experiencers, whereas the *rheme* signals actions and events. Sometimes, the *onoma* is represented as content, and the *rheme* is represented as typically having an enunciative function (Spina, 2002; for an overview of the whole tradition, see Sandmann, 1979).

An underlying opposition has also been suggested for the notions of Theme and Rheme, as is found in European functional linguistics and text linguistics (*see* **Halliday, Michael A. K. (b. 1925)**; **Prague School**). In these fields, the pair is defined according

to functional principles that are based on the speaker's needs and communicative aims. Mathesius (1983: 102) maintained, "Every bipartite utterance is composed of two components, the first of which expresses something relatively new and contains what is asserted by the sentence... The second part of the sentence contains the basis of the utterance or theme, the psychological subject according to earlier terminology, i.e. things relatively familiar or most readily available to the speaker as the starting point." The order assigned here to the first and second parts invokes a hierarchy of importance, not some linear property of the syntagmatic structure. However, the linearization of Theme and Rheme is an area that has been investigated widely by Mathesius and other Prague School theorists (see Mathesius, 1924, 1939, 1941–1942; Daneš, 1985; Sgall *et al.,* 1986; Firbas, 1992).

The categories described by the Prague School are classical tools in discourse analysis that have precedents in philosophical thought concerning textual hermeneutics (see Schleiermacher, 1988). In actual fact, no textual analysis is possible without assuming a hierarchy of informative importance for parts of the texts with respect to the speaker or to the interlocutor. However, the Prague School and North American definitions are not as rigidly separated as one might think. Mathesius (1939: 174), for example, assimilated "that which is known in a given situation" to the "utterance's starting point ... from where the speaker begins," defining the utterance's nucleus as "that which the speaker asserts with respect to the starting point ... or taking it into consideration."

However, no matter how many early versions of these concepts and terms can be found, in modern linguistics, the Topic-Comment and Theme-Rheme pairs must be understood within the scientific traditions in which they were developed and in which they continue to be used (with some subsequent modifications). Even allowing for the differences between the North American and European scientific environment, both use linguistic concepts that have been influenced by schools of pragmatism. These trends have left their mark in various ways on functional approaches of the 20th century and, in certain respects, also on some fields of North American structuralism. In fact, the definition of both of these pairs assumes that the functioning of the utterance-act or of the discourse/text is a key criterion. All 20th-century models are based on the notion of functioning (the First and Second Prague Schools, Halliday, and Chafe), but the biases of each favor either the pragmatic or the semantic dimension. In the Prague tradition, the Theme and the Rheme are considered to be the units of the actual articulation of the sentence (Functional Sentence Perspective). This concerns "the way in which the sentence is inserted into the real context from which it comes" (Mathesius, 1939: 174). Indeed, "it is only the moment of actuality that creates a sentence from the words" (Mathesius, 1924: 171).

Topic and Comment, Subject and Predicate

Lack of Alignment between Pragmatic Functions and Semantic and Grammatical Functions

In many approaches, a correspondence (if not an exact correlation) is assumed between Topic-Comment and Subject-Predicate (see Sapir, 1921; Strawson, 1974; Lambrecht, 1994). In developing a "Relevance Principle," Strawson (1974: 97) observed, "Statements or the pieces of discourse to which they belong have subjects, not only in the relatively precise sense of logic and grammar, but in a vaguer sense with which [one] shall associate the words 'topic' and 'about.'" Moreover, he noted that "stating is not a gratuitous and random human activity. We do not, except in social desperation, direct isolated and unconnected pieces of information at each other, but on the contrary intend in general to give or add information about what is a matter of standing current interest or concern" (Strawson, 1974: 97; cf. also Lambrecht, 1994).

Yet, the association of Topic-Comment and Subject-Predicate is problematic, because alongside the obvious similarities, there are also considerable differences. The first similarity lies in the actual nature of the relationship between the two parts. The question of whether the Subject is dependent on the Verb (Predicate) or whether the Predicate is dependent on the Subject has been discussed at length, and valid reasons have been proposed to support both theories (see Matthews, 1981; Graffi, 2001). However, it seems plausible to think that in each case both of the parts are necessary for the larger construction that they form (enunciation for T-C and phrase for S-P) and that they correspond and are mutually dependent (for more information on this model of interdependence or 'solidarity,' see Martinet, 1965 and 1985). There can be no Predicate without a Subject, and there can be no Subject without a Predicate; Predicate and Object, in contrast, are not linked by this kind of reciprocal relation. A second aspect that the two pairs of functions have in common concerns the canonical (or prototypical) semantico-pragmatic properties of each of the two parts: one carries reference, and the other carries the utterance-act/predication (for a philosophical account, cf. Strawson, 1974).

The differences are no less significant. Topic-Comment (T-C) or Theme-Rheme (T-R) is a representation that is anchored not at the syntactic level, but rather at a more general dimension defined as rhetorical-pragmatic (see below). In fact, it seems necessary to bring back into focus the traditional distinction among 'utterance,' 'proposition,' and 'sentence' as constructions that belong to three different dimensions; namely, the pragmatic, semantic, and syntactic. The T-C (or T-R) pair is concerned with the level of the utterance-act, and it constitutes its basic articulation. Its terms therefore need to be kept distinct from both Predicate-Arguments and Subject-Predicate, whatever similarities might exist between them. The utterance-act is defined by the speaker's communicative intention or, in other terms, by his or her desire to mean something. This type of component is not included in either the syntactic configuration or in the propositional scheme. A simple utterance such as:

(1) John loves the sea

is not represented fully by either the phrase structure of traditional constituent analysis (or any more recent version of generative grammar):

(2) [S[NP *John*] [VP[V *loves*] [NP[Det *the*] [NP *sea*]]]]

nor by the propositional scheme:

(3) p (a, b), where p = 'to love', a = 'John', b = 'sea'

but by a more complex structure that can be informally expressed as follows:

(4) as for John, I am telling you that John loves the sea

The representation in (4) demonstrates that the syntactic configuration and the propositional scheme can only be considered subparts of the whole utterance. In particular, the p component of (3) forms a lower-level predicate, the semantic representation of which is defined by three properties: bivalency, the inherent lexico-semantic features of 'to love', and the capacity to combine with arguments that have specific semantic features. In contrast, the fact that an utterance like (1) has a pragmatic representation in which a declarative statement appears does not concern the propositional predicate: It is not something that is included in the properties of the predicate 'to love,' and neither is it part of its relations with the arguments 'John' and 'sea.' The declarative statement 'I am telling' must be represented as a predicate of a higher level. The differences between the representations of the syntactic structure (2), the proposition (3), and the utterance-act (4) can be expressed in relation to the well-known distinction between 'mood' (*modus*) and the statement's content structure (*dictum*; see Bally, 1944; Graffi, 2001). The constituent that has predicative function in a sentence configuration and the predicate of the logical-semantic scheme are part of the statement's content structure. The higher predicate 'I am telling' is the mood of the utterance-act. It is not necessarily realized by phrase structure or by any other kind of segmental shape; in many languages in fact, it is normally realized by intonation. Yet, in order for an utterance-act to be formed, it must be present in any case.

Based on this schema, one can say that the division of Topic and Comment constitutes the basic structure of representations like (4). The relationship between T and C is defined by a predication at a higher level than that belonging to the predicate 'to love.' This kind of predication can be represented by the illocutionary force of statement. The Topic function does not coincide with the Subject any more than the Comment does with the Predicate. Topic and Comment belong to an organizational level that is logically higher, and their relation is determined by the declarative mood.

Significant proof of this theory is found in a well-known empirical feature that distinguishes subordinate clauses from main clauses. Only the latter can have a Topic-Comment articulation, whereas the former do not. In fact, the illocutionary force of statement is a fundamental part of the representation of main declarative clauses, whereas subordinate clauses have only the statement's content structure in their representations. The fact that, in some approaches, like the Second Prague School (see Svoboda, 1968; Firbas, 1992), subordinate clauses have been divided into Theme and Rheme illustrates a further aspect of the conceptual difference between the two pairs of terms.

Representations like (4) can account not only for utterances like (1), where the statement's content structure is made up of a Subject – (transitive) Predicate structure but also utterances where the statement's content structure has Subject – (intransitive) Predicate structure, as in (5) with the corresponding representation of the utterance-act (6):

(5) John is coming

(6) as for John, I am telling you that John is coming

Yet, not all utterances with single-arguments in the statement's content structure have a representation like (6). So-called presentative or thetic utterances like (7):

(7) JOHN is coming

that are marked in English by a focal accent on John and in other languages by the order VS do not easily conform to the Topic-Comment split. According to a line of thought that has gained wide consensus, utterances like (7) lack the Topic-Comment articulation and the Theme-Rheme split. They can be analyzed according to two different interpretations, depending on the context. In one, *John* is in Focus (in this case, the utterance has the pragmatic presupposition that someone will come), and in the other, the whole statement's content structure is in Focus (in this case, the pragmatic presupposition can be expressed by the question "what's happening?"). In the latter interpretation, single-component structures like (7) are opposed to bipartite T-C or T-R structures. This tradition of linguistic thought was influenced by the distinction made by Kant between *a priori* 'analytic' judgments and *a posteriori* 'synthetic' judgments, which are typically bipartite, and existential judgements that have no predicate. Marty reinterpreted the Kantian distinction by opposing "categorical" judgments that are bipartite and "thetic" judgements that are simple, having only one member (see Ulrich, 1985).

In this respect, there is an interesting difference between some Topic-Comment models that are in wide use today and the Theme-Rheme models from the Prague School. According to the first type, Topic is absent because this type of function needs to be realized by a constituent that has a high position in the referentiality hierarchy; canonically, this would be a NP. According to the second type, in contrast, the bipartite articulation is legitimate if (7) is interpreted as having only *John* in Focus: The verb 'to come' would be the Theme, and *John* would be the Rheme.

However, these analyses are problematic. The two interpretations of (7) could correspond to the representations of the utterance-act (8) and (9):

(8) I'm saying that the person who is coming is John

(9) I'm saying that what is happening is that John is coming

Yet, such representations can be considered, respectively, equivalent to the following:

(10) As for who is coming, I'm saying that the person who is coming is John

(11) As for what is happening, I'm saying that what is happening is that John is coming

The fact that the Topics of utterances like (7) are not realized in the linguistic structure does not prevent the analysis of the utterance-act from containing representations that make them explicit; the utterance-act also includes elements that are not verbally expressed but present in the context. This has at least two implications: (1) the distinction between elements that carry reference and elements that carry the predication, at the pragmatic level, might be more complicated than is often thought, and (2) the T-C and T-R models can be transcoded.

It becomes particularly obvious that we need representations of the utterance that are not limited to the canonical forms of configurational and propositional representation when we look at utterances whose syntactic structure contains constituents that do not have traditional Grammatical Functions. Utterances with various types of left dislocation and hanging topics, like (12), (13), and (14)

(12) John, I saw him yesterday

(13) John, I lent him the book

(14) John, his house is a complete mess

do not have identical functions: The Subject and Object (either direct or indirect) functions evidently belong to a level of representation different from that at which the Topic function is found. This question has recently been tackled in the so-called discourse configurational models of generative grammar (cf. Kiss, 1995). These models define two discourse semantic functions, Topic and Focus, the first "serving to foreground a specific individual that something will be predicated about" and the second "expressing identification" (Kiss, 1995: 6). Although this may seem a major departure from traditional generative models, which define the Topic function in purely configurational terms, the main orientation still remains on the study of how the two discourse functions are expressed through a structural (i.e., configurational) relation. In other terms, the discourse configurational models only account for the structural projections of a Function that itself belongs to another level of representation.

What has been said so far allows further consideration of the parallels between the Subject-Predicate and the Topic-Comment functions. The former defines the sentence and the latter the utterance. Both relations are crucial for functioning, at different levels. Through them, what were simple groups of elements become meaningful units at the sentence-level and carry indexical values at the utterance-level. It is at the latter level that they properly become communicative units.

Structural Implications of the Differences among Pragmatic, Semantic, and Grammatical Functions

The pragmatic and semantic differences discussed here have significant consequences for the structural level. They also involve different formal properties. In

languages in which the Subject function is morphologically encoded (this is realized by the relevant Noun Phrases and/or by the heads of Verb phrases of which they are made), such encoding does not necessarily match the structural projection of the Topic function. For example, if the linguistic system has Case marking on the Subject, this might not be required for the Topic, or it could be realized by Case marking that is not the same as the Subject's marking. Similarly, if a language has agreement between Subject and Verb, the same might not apply to the constituents that realize the Topic and Comment functions. In general, the range of types of constituents that can have the Topic function (or the Comment function) is larger than the range of types of constituents that can have the Subject or Predicate functions.

Another group of structural properties that distinguish Subjects from Topics concerns the movement properties of the relative constituents within the sentence. In certain models, the Topic function is determined by linearity. It is associated with the first or one of the first positions of the proper domain of the sentence or with an extra-sentential position to the left of the proper domain (see Graffi, 1994; Dik, 1997). The movement of the Topic constituent to another position in the sentence, in particular toward final or extra-sentential positions to the right of the proper domain (the Tail), generally leads to the constituent losing the Topic (or Theme) function. Nevertheless, the fact that there is a significant statistical correspondence across the world's languages between the basic Subject position and the Topic function appearing in the initial position (see Comrie, 1981; Tomlin, 1986) cannot be taken as conclusive proof that Subjects and Topics should be considered to be structurally equivalent. In fact, in many languages the range of grammatical functions whose constituents can occupy the initial positions of the proper domain of the sentence is not limited to the Subject function alone. One need only think of relatively common processes, such as left dislocation of direct or indirect Objects.

Finally, there are also substantial differences in the referential endophoric properties. In many languages, the grammatical Subject constituents have control properties over anaphors that the Topic constituents do not have. All the structural differences mentioned so far have implications for both typology (cf. the Topic-prominent vs. Subject-prominent language dichotomy presented by Li and Thompson, 1976 and widely used in typology) and Universal Grammar (see the important study of Keenan, 1976).

To sum up, the set of the structural properties defined by T-C, T-R and the set of structural properties defined by Subject-Predicate intersect, but do not wholly overlap. In particular, the set of constructions that realize T-C functions is larger than the set of constructions that realize the syntactic functions Subject-Predicate.

Similarities and Differences among Various Models

The concept of Topic as an element that limits or restricts the field of the predication (Chafe, 1987) is based on structural properties (for example, the fact that the Topic needs to precede the predicate) and lexico-semantic properties (specifically, contiguity and isotopy). The definition of Theme as the 'Base' or starting point of the utterance (Mathesius), or the part that conveys the lowest level of Communicative Dynamism (Firbas, Svoboda), depends on linear principles of functioning that are to some extent independent from the grammatical organization. To a certain extent, one can say the same for the GIVEN-NEW and for the KNOWN-UNKNOWN parameters, all of which are used widely in text linguistics. These parameters are based on the lexico-semantic and compositional properties of units in relation to larger sections of text; however, they also constitute pragmatic categories related to the functioning of the utterance-act. Similar observations can be applied to the notion of 'Focus' in Tagmemics (see Pike, 1982) and the recent versions of the Focus function (see Rebuschi and Tuller, 1999 and (*see* **Focus**), which show similarities to the notions of Comment and Rheme. This is also the case for the definitions of Topic either as the center of attention (see Chafe, 1976) or as a most accessible element (see Givón, 1985; Chafe, 1994) that are based on cognitive properties.

In many models, two different pragmatic and semantic approaches are merged: one according to which the meaning and information of units depend on their referential indexes, determined by the context, and the other according to which the meaning and information of an utterance depend on the 'functioning,' or to be more precise, on the actual dynamics with which the speakers plan and perform the discourse in relation to the listeners. It is generally the case that in all the models the relationship between meaning and information remains an open question (but see the interesting proposals presented by Bar-Hillel and Carnap, 1964; Harris, 1991). However, the centrality assigned to indexical coordinates to a greater or lesser extent (see Bar-Hillel, 1954, 1970) is a criterion that appears to have been employed in a more general way than the concept of 'functioning,' albeit at different levels of theoretical development. This kind of characteristic in fact can be

used as a distinctive criterion to determine the degree of pragmatic orientation of a model. Another criterion for pragmatic orientation concerns the speaker-listener dimension: Base, GIVEN, NEW, Focus, accessible element, and center of attention are all categories related to the speaker and the listener.

However, a question emerges that has so far remained unanswered: whether the categories defined according to the speaker are the same as those defined according to the listener. The fact is that the two types of categories do not necessarily coincide: what is Topic for the speaker might not be for the listener and vice versa. In fact, an important difference among the functional models concerns the bias toward production or comprehension of the utterance/text. If concepts like GIVEN and NEW or the hierarchy of communicative dynamism seem to be ambivalent, 'Base' perhaps displays a bias toward production and 'the most accessible element' is biased toward comprehension. The bias often remains implicit, but has important consequences for the modeling itself.

Topic-Comment Articulation and Spoken Discourse

Two questions often discussed concern the hypotheses that the Topic-Comment articulation is characteristic of spoken discourse and that it has a more basic character than the Subject-Predicate articulation. Indeed, several psycholinguistic studies seem to show that in the process of language acquisition the structures that have the grammatical properties of Subject-Predicate appear after the structures that are grammatically heterogeneous and that are reducible to the general Topic-Comment articulation (cf. MacWhinney and Bates, 1978 and, for second language acquisition, Klein and Perdue, 1992). There is no question that analyses of oral corpora of languages that have grammatically articulated Subject and Predicate show numerous structures that do not conform to patterns in which the Topic is a Subject NP and the Comment is a canonical VP. Yet, the two hypotheses proposed are difficult to test empirically. One reason is that phenomena with very diverse structural characteristics are often grouped together under the label of T-C, which means that results obtained across a variety of research areas are incompatible.

Statistical calculations have been done on a range of languages through corpora in an attempt to determine the occurrence rate of structures that are traditionally considered to be examples of the T-C split, such as hanging topics, left dislocations, etc. However, it is questionable whether the results obtained in this way can definitively prove the prevalence of such structures in spoken discourse because of the great variety of linguistic and extra-linguistic conditions that can apply to both spoken texts and written texts. To sum up, without excluding the fact that certain structures like (13) and (14) are in reality characteristic of unplanned spoken discourse, in general the hypotheses discussed may have methodological rather than theoretical value. In the analysis of spoken discourse, categories, such as Topic-Comment or Theme-Rheme, may prove to be more useful than purely syntactic categories.

Cognitive, Interactional, and Textual Dimensions

The representation of Topic and Comment in cognitive terms, common in some North American functional schools, has important precedents in the history of linguistic thought. During the second half of the 19th century, a lively debate emerged about the notion of Subject and Predicate, in which the grammatical categories were defined psychologically by some scholars (see Graffi, 2001). Paul (1920: 87) defined the Psychological Subject as "the first retrievable complex of psychological representations in the consciousness of the speaking and thinking being" and the Psychological Predicate as "the second [complex of psychological representations] that is connected to the first." Although he acknowledged that the grammatical Subject and Predicate do not always correspond to the psychological Subject and Predicate, Paul nevertheless believed that "the grammatical relations are based on the psychological relations" (1920: 111). Interest in the psychological dimension has always been present in linguistics, in particular in certain functional schools. However, in the Prague School, psychology was considered to be a discipline entirely auxiliary to linguistics (Mathesius, 1924).

In North American functional studies, topics have been defined at sentence-level (the micro-level) as constituents that have referential features or rather as 'participants' in the semantic scheme (see Foley and Van Valin, 1984; Givón, 1985; Chafe, 1994; Lambrecht, 1994). This definition has often been used in linguistic typology, particularly after Comrie (1981; see Premper, 2001). Discourse topics have been defined as "aggregate[s] of coherently related events, states, and referents that are held together in some form in the speaker's semi-active consciousness" (Chafe, 1994: 121). Givón (1985) believed that the definition of Topic as an atomistic, singular, and discrete unit at the sentence-level (the so-called micro-topic) should be replaced by a model that represents a plurality of sentence topics and the permanence or continuity of these text participants. In each case, these studies were based on a semantic assumption about the

representation of ideas; namely, that events and states and the referents that participate in them make up the basic cognitive network of the speakers and the listeners (see Givón, 1985; Chafe, 1994). This model has an equivalent in the so-called ontologies in use today in artificial intelligence. The analyses of Topic continuity can in fact have numerous applications in this sector and also in computational linguistics.

Topic and Comment: Between Reference and Relationship

The property traditionally ascribed to the Topic function – namely, its capacity to contain elements that carry reference – is neither a necessary nor a sufficient condition for topicality. The fact that Topic has recently been reinterpreted in relation to a referential hierarchy of access to the function (Topics tend to be elements high up on the hierarchy of referentiality) shows that it is not a necessary condition. For example, there are adjectives or verb forms with no finite marking that can perform the Topic function in many languages. Moreover, not all referential elements are Topics. Referentiality simply defines a relation between an element and an exophoric context (that is to say, extra-linguistic) or an endophoric context (that is to say, intratextual). In contrast, topicality is a purely textual function, linked to the flow of information in the text: For an element to be a Topic, it must be part of an informative progression where something is being said about it or, more precisely, more information is being added about it. In other words, for an element to be a Topic, it must be true that other information will be added about it. As has been said, the models of textual Topic-continuity rely on referential characteristics, whereas sentence-oriented models are based on the relational characteristics of Topic and Comment. In the latter, the similarity with the syntactic functions of Subject and Predicate – also inherently relational – is therefore emphasized.

Topic Chaining Constructions

W A Foley, University of Sydney, Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

When people speak, they do so within a context that includes previous speech, of themselves, of other interlocutors, and even of long-dead ancestors, in clichés, proverbs, or even fables. This context of speaking, together with wider sociocultural knowledge, is the background against which people construct and interpret the meaning and relevance of new utterances so that the utterances cohere to make up an intelligible discourse. A discourse is not merely a set of sentences randomly strung together but is, rather, a structural series, the development of which constitutes a coherent whole and is recognized as such by speakers of a language. Some of the crucial principles that guide this process of structuring discourse are those concerning informativeness. Following Levinson (2000), we can define the information content of an utterance in terms of the number of possible states of affairs it effectively rules out. So, in giving instructions to a waiter in a crowded restaurant, it is likely that *bring this to the table of the middle-aged bald men* is more informative than *bring this to the table with men* because it effectively rules out more tables for the waiter. But there is clearly a limit to the level of explicitness desirable in order to achieve informativeness. For example, more and more restricting details could be added, for example, *bring this to the table with the middle-aged bald men, all of whom are drunk and are having a bucks' night for the one in the red jacket*, and so on, but this quickly runs afoul of practical economic limits on utterance size. To optimize the efficacy of both informativeness and economy, speakers of natural languages employ a set of heuristics for the production and interpretation of utterances in discourse (Grice, 1989; Horn, 1989; Levinson, 2000), two in particular being relevant here: (1) if something is stereotypical or expected, express it simply; and conversely, (2) if something is expressed in a more complex, unusual, or marked way, the stereotypical or usual interpretation should be avoided. These principles ride the razor's edge between informativeness and economy, in that things taken for granted in terms of the effective

Abstract:

This article presents an overview of the problems and methods relating to the definition of Topic and Comment. Special attention is devoted to the relationship of Topic-Comment to Subject-Predicate and Predicate-Arguments. It is argued that Topic and Comment belong to a level of representation that is logically higher than that of Subject-Predicate and Predicate-Arguments and that their interdependent relation is determined by Mood.

Biography:

Rosanna Sornicola is Professor of General Linguistics at the Department of Modern Philology of the University of Naples Federico II, where she is also the Director of the European Master's Degree in Linguistics. She graduated in Linguistics and Modern Philology at the University of Naples in 1975. She was Visiting Fellow at Wolfson College (Cambridge) in 1983 and 1987, Visiting Researcher at the Department of Linguistics of the University of California (at Berkeley) (1985), and Visiting Researcher at the Department of Italian of the University of California (at Los Angeles) (1988). She is a member of Wolfson College of the University of Cambridge. She was Visiting Professor at the University of California at Los Angeles (1990), Manchester University (1990), Girona (1996), and Gand (1999), and has lectured in many other European universities.

She has worked for several international research projects (the EUROTYP project of the European Science Foundation, 1990–1996; the project on Diachronie, diatopie, diastratie, diaphasie des langues romanes directed by Eugenio Coseriu and Rika Van Deyck, 1993–2001) and is currently involved in various research projects on Italian sociolinguistics and dialectology in cooperation with the Department of Linguistics of the University of Turin and the Romanisches Seminar of the University of Heidelberg.

She is member of the scientific board of the reviews *Cahiers de linguistique romane, Lingue e Linguaggi*, and *Revue de linguistique romane*, and is coeditor of the journal *Bollettino Linguistico Campano*. She has been member of the Executive Committee of the International Society for Historical Linguistics, of the Scientific Bureau of the Societé internationale de linguistique et philologie romanes, and since 1999 has served as President of the Società di Linguistica Italiana.

Her research interests concern phonetic, phonology, syntax, and pragmatics of spoken language, the relationship between spoken and written discourse, Italian and Romance sociolinguistics and dialectology, synchronic and diachronic typology, and history of linguistics (especially the history of European functionalism).

Her publications include the following books: *La competenza multipla* (Napoli, Liguori 1977), *Sul parlato* (Bologna, Il Mulino 1981), *Il campo di tensione. La sintassi della Scuola di Praga* (coeditor with Aleš Svoboda, Napoli, Liguori 1992), *The virtues of language: history in language, text and literature* (coeditor with Dieter Stein, Amsterdam, Benjamins 1998), *Stability, variation and change of word order patterns over time* (editor with Erich Poppe and Ariel Shisha Ha-Levy, Amsterdam, Benjamins 2000), *Langue écrite, langue parlée dans le passé et dans le present* (coeditor with Rika van Deyck and Johannes Kabatek, Tübingen, Narr, forthcoming). She is also author of many articles published in books and journals.

When people speak, they do so within a context that includes previous speech, of themselves, of other interlocutors, and even of long-dead ancestors, in clichés, proverbs, or even fables. This context of speaking, together with wider sociocultural knowledge, is the background against which people construct and interpret the meaning and relevance of new utterances so that the utterances cohere to make up an intelligible discourse. A discourse is not merely a set of sentences randomly strung together but is, rather, a structural series, the development of which constitutes a coherent whole and is recognized as such by speakers of a language. Some of the crucial principles that guide this process of structuring discourse are those concerning informativeness. Following Levinson (2000), we can define the information content of an utterance in terms of the number of possible states of affairs it effectively rules out. So, in giving instructions to a waiter in a crowded restaurant, it is likely that *bring this to the table of the middle-aged bald men* is more informative than *bring this to the table with men* because it effectively rules out more tables for the waiter. But there is clearly a limit to the level of explicitness desirable in order to achieve informativeness. For example, more and more restricting details could be added, for example, *bring this to the table with the middle-aged bald men, all of whom are drunk and are having a bucks' night for the one in the red jacket*, and so on, but this quickly runs afoul of practical economic limits on utterance size. To optimize the efficacy of both informativeness and economy, speakers of natural languages employ a set of heuristics for the production and interpretation of utterances in discourse (Grice, 1989; Horn, 1989; Levinson, 2000), two in particular being relevant here: (1) if something is stereotypical or expected, express it simply; and conversely, (2) if something is expressed in a more complex, unusual, or marked way, the stereotypical or usual interpretation should be avoided. These principles ride the razor's edge between informativeness and economy, in that things taken for granted in terms of the effective

informativeness of the utterance tend toward attenuated expression, whereas those that cannot favor a fuller enunciation.

These principles ground what is typically called the information structure of a sentence (Lambrecht, 1994; King, 1995; Kiss, 1995) and its articulation in terms of the notions of topic and focus. Lambrecht (1994: 131) defined topic as the entity an utterance is about. Topics are typically already presupposed, established in the discourse context (or pragmatically accessible, in Lambrecht's terms) and in this are in marked contrast to focus, the asserted component of the utterance (Lambrecht, 1994: 213). In terms of the grounding heuristics, topical constituents, as presupposed/established, tend toward attenuated formal realizations, whereas focused constituents, as the main asserted point of the utterance and hence typically unexpected or noteworthy, favor fuller formal realizations. Bresnan (2001), building on Givón (1976, 1983) builds a hierarchy of NP types, starting with the most attenuated realizations, zero (i.e., no overt phonemic form), through affixes, clitics, free pronouns, and up to full noun-headed NPs, and links these through harmonic alignment (Aissen, 2001) with the notions of topic and focus, so that the more attenuated NP types are likely to be topics and the fuller ones are likely to be focus.

Clearly, the most attenuated realization, zero, has the strongest claim on topic status; the simplest possible expression is interpreted as the most presupposed, identifiable referent. Languages exhibit a phenomenon called topic chaining (Li and Thompson, 1979), in which a topic is established as a full NP in the first clause in a discourse unit, and this then functions as the referent for the topics in the succeeding clauses, with attenuated realizations as zero or pronominals. Zero is obviously the most extreme realization and potentially presents a problem of recoverability: if there is no overt trace of the topic in the clause, how can we clearly identify its function? Some languages, such as Chinese (Mandarin Chinese) or Watam of New Guinea, are quite free in their use of zero realization; NPs in a range of syntactic functions can be realized by zero if they are highly accessible topics. This often results in potential syntactic ambiguity in the delineation of syntactic functions in a clause, especially if multiple zero realization of topical NPs is permitted in a single clause, as in Watam, although this problem is typically resolved by contextual cues. Other languages are more restricted; English, for instance, allows zero realization only for subject NPs (Figure 1). Note that, due to the syntactic restriction, there is no ambiguity here. Note further that utterances in languages with such restrictions are actually more informative (in the sense previously defined) than those without, in that they formally rule out more possible states of affairs.

Languages with restrictions on the type of syntactic functions that can be realized by zero anaphora often have voice systems. Voice systems permute the syntactic structure of the clause so that a choice of syntactic functions can be accessible to the privileged syntactic constituent that is the target for zero realization, called the pivot. The pivot notion then represents a syntacticization of the notion of topic. It is the unmarked slot for topics, and, because zero realization is restricted to highly accessible topics, this is only possible in the pivot function. Voice systems then allow topics of an array of syntactic functions to be accessible to the pivot function and hence have the option of zero realization.

Languages can be classified into three types in terms of their pivot choices and voice systems. English illustrates the most common and familiar type. In this case, the basic unmarked choice for the pivot of a transitive verb is the actor participant, and clauses with such an unmarked and expected choice are in the neutral active voice. If the undergoer of a transitive verb is the topic of a clause and target for zero realization, then an alternative clause structure, the passive voice, is employed, making the undergoer the pivot and demoting the actor to a peripheral adjunct position, as in the following active-passive pair:

(1a) the boy hit the ball
(1b) the ball was hit by the boy

In languages of the English type, a wide range of constructions that require pivots as the target of zero realization of highly presupposed topics employ passives when the pivot is the undergoer of a transitive clause (Figure 2).

The second type is exemplified by ergative languages (Figure 3B) like the Mayan language Mam (England, 1988) or the Australian language Dyirbal (Dixon, 1972). In these languages the unmarked pivot choice is the undergoer participant of a transitive verb, the opposite of English (Figure 3A). The undergoer as the pivot is then the target of zero realization in unmarked utterances, as in Dyirbal (Figure 4).

If the actor is highly topical and the target of zero realization, it cannot simply be elided. Rather,

Figure 1 English zero realization for subject NPs.

Figure 2 In English, constructions that require pivots as the target of zero realization of highly presupposed topics employ passives when the pivot is the undergoer of a transitive clause.

Figure 3 (A) English vs. (B) Mam and Dyribal (ergative languages), in which the unmarked pivot choice is the undergoer participant of a transitive verb.

Figure 4 In Dyirbal, the undergoer as the pivot is then the target of zero realization in unmarked utterances.

Figure 5 The antipassive, the mirror image of the passive puts the undergoer in a peripheral adjunct position (dative case in Dyirbal); the actor becomes accessible to zero realization.

Figure 6 In Tagalog, there is no strong preference for either the actor or the undergoer to be the pivot of the clause; either can be according to wider syntactic or textual constraints.

a construction called the antipassive, the mirror image of the passive, is required, which puts the undergoer in a peripheral adjunct position (in the dative case in Dyirbal) and the actor becomes accessible to zero realization (Figure 5). Ellipsis across conjoined clauses is restricted to pivot NPs. The sentence in Figure 4 is grammatical because it is the undergoer participant of the transitive verb *βʊʃαλ-* 'see,' the pivot choice, which is elided (note that, as expected, the literal English translation of the sentence in Figure 4 is ungrammatical because of the opposite choice for the pivot: **the woman came and the man saw ϕ*). The sentence in Figure 5A is ungrammatical because the actor has been elided: actors are not the pivot choices of transitive verbs in Dyirbal and are therefore not targeted for zero realization (the English translation is perfectly grammatical, as we would predict). In order to communicate the meaning

Figure 7 In Tagalog, the semantic role of the controlling pivot of the first clause may be (A) actor or (B) undergoer.

of Figure 5A grammatically in Dyirbal, an antipassive construction must be used, as in Figure 5B. This places the actor in the pivot function, and it is therefore a proper target for ellipsis.

The final type of voice system is widespread in Western Austronesian languages and is here exemplified by Tagalog. These are symmetrical pivot languages in which there is no strong preference for either the actor or the undergoer to be the pivot of the clause; either can be according to wider syntactic or textual constraints. In Tagalog, core subcategorized arguments are marked with the preposition *ng* and adjuncts with *sa*. The pivot has the preposition *ang* and the verb takes a series of affixes to indicate the actor or undergoer semantic function of the pivot (Figure 6). Note that either the actor or undergoer participant can be the pivot, the choice being signaled by different affixation to the verb: the infix *-um* -for actor = pivot and the suffix *-in* for undergoer = pivot. Note further that regardless of which participant becomes the pivot, the other argument remains core and marked by *ng*.

This is in marked contrast to asymmetrical languages such as English and Dyirbal in which marked constructions such as passive or antipassive must be used when anything other than the normal pivot choice is made, forcing the recasting of the clause, with the erstwhile pivot appearing as a peripheral adjunct NP or disappearing from the clause entirely. Clearly, languages such as English and Dyirbal are asymmetrical; one participant type is strongly favored to be the pivot and, if it fails to assume this function, it ceases to be core subcategorized. This is not the case in symmetrical languages such as Tagalog in which either choice is possible, with no major disruption to clause structure regardless of which is chosen.

Tagalog pivots have many of the same properties we have come to expect of them from English and Dyirbal (Figure 7). The topic is established as an overt pivot NP in the first clause and then is targeted for zero realization in the second clause of both examples. The pivot of the second clause is obligatorily realized as zero if it is coreferential with the pivot of the first clause. Note that the semantic role of the controlling pivot of the first clause is irrelevant; it may be the actor (Figure 7A) or the undergoer (Figure 7B), but it must be the pivot. The example in Figure 7A cannot be construed with a meaning that it was the man who left; that is, only the pivot is the possible antecedent of the zero anaphora in the second clause.

Toporov, Vladimir Nikolaevich (b. 1928)

N N Kazansky, Institute for Linguistic Studies, St Petersburg, Russia

© 2006 Elsevier Ltd. All rights reserved.

Vladimir Nikolaevich Toporov is a Russian philologist, linguist, and specialist in Indo-European linguistics, semiotics and history of culture. His research covers topics in Slavic, Baltic, Indo-European, and Russian linguistics as well as general linguistics, poetics, folklore, mythology, and culturology. Toporov was one of the pioneers of semiotic research in the USSR. His semiotic views were formed in the course of his occupation with linguistics of Slavic and other Indo-European languages. Toporov was a permanent member of Tartu semiotic school and a contributor of all issues of *Papers on Sign Systems*. Among the works written by him are structural descriptions of Sanskrit and Pali grammar, a few studies on Hittite texts, an etymological dictionary of Old Prussian, and numerous etymological papers. Toporov's Ph.D. dissertation was devoted to the expression of locativity in Slavic and Baltic languages; in 1989 he was conferred a doctoral degree (doctor habilis) *honoris causa* for the total of his published works.

Born in Moscow (Russia) on August 8, 1928, Toporov is married to Tatjana Ja Elizarenkova, a specialist in Indic culture and languages, and a translator of Rig-Veda into Russian. His two daughters are philologists: Tatjana V. Toporova, an author of three books, is a specialist in old Germanic languages; Anna V. Toporova deals with Romance languages. Toporov works at the Institute for Slavistics (Russian Academy of Sciences), where he has been a member since 1990. His research was marked with a number of prestigious awards, including the National Award of USSR, the Alexander Solzhenitsyn Award, and the Andrej Belyj prize.

Toporov graduated from the Moscow State University; while in Michail N. Peterson's class his studies included Indo-Aryan, Baltic, and other Indo-European languages; professors Nikolaj K. Gudzij and Piotr S. Kuznetsov also had a formative influence on his personality as a scholar. Further stimulus to the formation of Toporov's linguistic views was given by the visit by Roman Jakobson to Moscow in 1956; during this visit Jakobson gave a number of talks and introduced the audience to a totally new range of ideas, including recent trends in mathematics (for example, those of Khinchin). The same year, in September, Vyacheslav V. Ivanov, Piotr S. Kuznetsov, and Vladimir A. Uspenskij launched a seminar on mathematical methods, cybernetics, and semiotics at the Moscow State University. This seminar gave the impetus for the development of a mathematically rigorous way of linguistic thinking for many scholars, including Igor A. Melchuk and Vladimir Toporov. Toporov has maintained a keen interest in semiotics and the structural approach to linguistics all his life. Toporov took part in field expeditions, put a number of Ket texts on record (see Ketskij Sbornik, 1969) and worked on a general problem of genetic and areal relations between the Paleoasiatic languages of Siberia and the languages of central and southern Asia (including Himalayan languages). As a result of these investigations he published a study on the linguistic geography of Yenisei and another one on the Iranian influence on the indigenous languages of Siberia.

The work done by Toporov on the problem of Slavic ethogenese deserves a special mention. In 1965, together with Oleg N. Trubachev, he published a book on the toponymy of the Dnepr area (Toporov and Ivanov, 1965); he also studied the toponymy of Moscow region, where he managed to trace a number of Baltic names (according to Toporov, Slavic languages are a branch of the Baltic language family).

Toporov published extensively on topics in Indo-European mythology, in particular, the basic myth concerning the storm-god slaying the serpent. In this connection Toporov undertook a comparison of a number of folklore motives and technical terms of Slavic and Indo-Iranian religious beliefs. He produced numerous articles for the encyclopedia *World Myths* (1981–1982, 1st edition), several studies of the

Vladimir Nikolaevich Toporov is a Russian philologist, linguist, and specialist in Indo-European linguistics, semiotics and history of culture. His research covers topics in Slavic, Baltic, Indo-European, and Russian linguistics as well as general linguistics, poetics, folklore, mythology, and culturology. Toporov was one of the pioneers of semiotic research in the USSR. His semiotic views were formed in the course of his occupation with linguistics of Slavic and other Indo-European languages. Toporov was a permanent member of Tartu semiotic school and a contributor of all issues of *Papers on Sign Systems*. Among the works written by him are structural descriptions of Sanskrit and Pali grammar, a few studies on Hittite texts, an etymological dictionary of Old Prussian, and numerous etymological papers. Toporov's Ph.D. dissertation was devoted to the expression of locativity in Slavic and Baltic languages; in 1989 he was conferred a doctoral degree (doctor habilis) *honoris causa* for the total of his published works.

Born in Moscow (Russia) on August 8, 1928, Toporov is married to Tatjana Ja Elizarenkova, a specialist in Indic culture and languages, and a translator of Rig-Veda into Russian. His two daughters are philologists: Tatjana V. Toporova, an author of three books, is a specialist in old Germanic languages; Anna V. Toporova deals with Romance languages. Toporov works at the Institute for Slavistics (Russian Academy of Sciences), where he has been a member since 1990. His research was marked with a number of prestigious awards, including the National Award of USSR, the Alexander Solzhenitsyn Award, and the Andrej Belyj prize.

Toporov graduated from the Moscow State University; while in Michail N. Peterson's class his studies included Indo-Aryan, Baltic, and other Indo-European languages; professors Nikolaj K. Gudzij and Piotr S. Kuznetsov also had a formative influence on his personality as a scholar. Further stimulus to the formation of Toporov's linguistic views was given by the visit by Roman Jakobson to Moscow in 1956; during this visit Jakobson gave a number of talks and introduced the audience to a totally new range of ideas, including recent trends in mathematics (for example, those of Khinchin). The same year, in September, Vyacheslav V. Ivanov, Piotr S. Kuznetsov, and Vladimir A. Uspenskij launched a seminar on mathematical methods, cybernetics, and semiotics at the Moscow State University. This seminar gave the impetus for the development of a mathematically rigorous way of linguistic thinking for many scholars, including Igor A. Melchuk and Vladimir Toporov. Toporov has maintained a keen interest in semiotics and the structural approach to linguistics all his life. Toporov took part in field expeditions, put a number of Ket texts on record (see Ketskij Sbornik, 1969) and worked on a general problem of genetic and areal relations between the Paleoasiatic languages of Siberia and the languages of central and southern Asia (including Himalayan languages). As a result of these investigations he published a study on the linguistic geography of Yenisei and another one on the Iranian influence on the indigenous languages of Siberia.

The work done by Toporov on the problem of Slavic ethogenese deserves a special mention. In 1965, together with Oleg N. Trubachev, he published a book on the toponymy of the Dnepr area (Toporov and Ivanov, 1965); he also studied the toponymy of Moscow region, where he managed to trace a number of Baltic names (according to Toporov, Slavic languages are a branch of the Baltic language family).

Toporov published extensively on topics in Indo-European mythology, in particular, the basic myth concerning the storm-god slaying the serpent. In this connection Toporov undertook a comparison of a number of folklore motives and technical terms of Slavic and Indo-Iranian religious beliefs. He produced numerous articles for the encyclopedia *World Myths* (1981–1982, 1st edition), several studies of the

mythological beliefs related to mushrooms, ladybird, beaver, bee, and on other religious faiths going back to Slavic paganism and Indo-European poetics (a summarizing work was Toporov and Ivanov, 1974). In several publications Toporov analyzed the structure of riddles and charms.

Since the 1960s, Toporov has published numerous works on Russian writers and poets of the 19th to 20th centuries and the poetics of their œuvre. Among this set of his works are studies on Pushkin and his predecessors (Zhukovsky, Batjushkov and Karamzin), on akmeists' poetry (with T. V. Tsivjan), and on intertextual connections between Russian and European writers (Pushkin and Goldsmith, akmeists, and Gérard de Nerval).

Topics in Old Indic classical literature have been addressed in Toporov's writing as well, for instance his 1998 book on Sudraka's *Mrcchakatika* (The little clay cart; Toporov, 1998a), his study of dialogue structure of Sophocles's *Oedipus Rex,* and his study of the plot in Vergil's *Aeneid* ('Aeneas: the man of his destiny').

Some of Toporov's works are devoted to the reconstruction of Proto-Slavic text (1998b), and the reconstruction of the earliest historical situation in Kiev (beginning of the 10th century), based on the letter from the genizah of Cairo synagogue.

Two characteristics of Toporov as an etymologist are, first, his attention to textual reconstruction (namely, the reconstruction of a sign system in general) and its possible fragments and variants; secondly, Toporov admits the possibility of multiple etymologies, whereby several stages of a word's semantic development and possible contexts can be reconstructed. Following the ideas of Benveniste, Toporov lays special emphasis on the coincidence in semantics between different traditions.

Torricelli Languages

M Donohue, National University of Singapore, Singapore

© 2006 Elsevier Ltd. All rights reserved.

The approximately 50 languages of the Torricelli are spoken in north Papua New Guinea. The family extends from the eastern Bewani mountains in Sandaun Province; through the Torricelli ranges to Maprik, where Ndu speaking villages reach through to the north coast; and continuing east of Wewak in Sepik Province in the Marienberg ranges and ground south of the Murik lakes, with a final outpost at Bogia in Madang province. The languages are remarkable for non-Austronesian languages in New Guinea for having a basic SVO word order, whereas the norm is SOV. They have been grouped into seven subgroups, whose internal constituency appears to be valid, although the seven-way division still awaits proof. The membership of the family as a whole appears to be accurate.

There are typically no phonetically unusual segments in Torricelli languages, and, although stress is frequently contrastive, reports of tonal differences are rare. The languages near Nuku share with the adjacent Ndu languages the presence of creaky or glottalized vowels, ranging from just one (/a/) to contrasts present on the whole vowel inventory. The vowel inventories tend to be large, with seven or eight vowels being not uncommon in the western languages (a typical inventory is /i e ɛ a ɔ o u ʉ/) and five or six vowels being more common in the east. The loss of velar segments in some western languages has led to the unusual case of languages without velar contrasts at all. Voicing contrasts are usually associated with prenasalization.

There is significant diversity within the family, and the Torricelli languages are also significantly different from most other languages of New Guinea. Although they all show SVO order, typically with prefixal agreement for the subject and suffixal agreement for the object and lacking case marking on (core) nominals – all features that are unusual in New Guinea – other details of their morphological and syntactic structure show considerable diversity. In the eastern languages, such as Monumbo and Arapesh (Bukiyip, also known as Muhiang), multiple class systems with extensive concord are found, whereas in the west only remnant traces of noun classification can be found in the synchronically irregular plural endings of One and Olo.

For example, in Bukiyip 'stone' is *utom* (SING) *utabal* (PL), showing the *-m* and *-bal* suffixes typical of class 5 nouns (compare this with a class 2 noun, such as 'village' *wa-bél* SING, *wa-lúb* PL). Adjectives show similar suffixes, agreeing in class and number with their noun, and verbs have cognate prefixes:

yopi-**mi** uto-**m** **m**-a-pwe agnú
'(the) good stone is there'

yopi-**bili** wa-**bél** **bl**-a-pwe agnú
'(the) good village is there'

In the western Torricelli language One, 'stone' is *toma* (SING) *tomu* (PL), showing an *-a* versus *-u* pattern, just as in 'flower' *sula* (SING), *sulu* (PL), indicating that, although it is a minority pattern, the alternations in 'stone' are regular. The word for 'village' *wapli* can be singular or plural, with the common *-li* plural suffix, but *wap* is only singular (this form is commonly found in compounds, such as *wap oi* 'village grounds, area'). Concord on other words is not as strong, however:

upo toma w-ae nu
'the good stone is there'

This sentence shows no agreement on *upo* 'good,' and only the general second/third-person singular *w-* on the verb 'sit, be at.' The same forms as are found in:

upo wapli w-ae nu
'the good village is there'

A few adjectives do show alternations:

plola toma w-ae nu
'the short stone is there'

plolu tomu n-ai n-e nu
'the short stones are there'

with variation for number (the verb 'sit' has irregular singular and plural forms). Different noun classes, however, do not show different agreement patterns. Using the same inflecting adjective, *plola*, with a different noun shows the same inflectional pattern:

plola wap w-ae nu
'the short village is there'

plolu wapli n-ai n-e nu
'the short villages are there'

There are also no differences in verbal morphology. Another striking aspect of the NP in One involves the lack of a fixed word order: Gen N as well as N Gen, Dem N as well as N Dem, and Adj N as well as N Adj are found, with only relative clauses being restricted to postnominal position.

Like most languages of New Guinea, there is no evidence of a voice system operating in any of the Torricelli languages, but applicatives are almost universal in the Torricelli languages, being found in at least fossilized form even on the more isolating

members of the family. In some languages the applicative and the verb 'give' show close similarities (One: *-ne* APPL and *an(e)* 'give'), whereas in other languages the two morphemes bear no obvious resemblance to each other (Olo: *-f(i)* APPL, *wa* 'give'; Arapesh *-'ma* APPL, *se'* 'give'). There does not seem to be a single historical source for the various applicatives attested in different branches of the family. An applicative is often required lexically by low-transitive verbs. One has *y-upa-**ne*** 'follow,' with a lexicalized applicative, for instance.

Serial verbs are a regular feature of Torricelli languages, although clause chaining is not. One, the westernmost Torricelli language has an unusual syntactic parameter setting whereby word order within the NP is free but the position of NPs and PPs within the clause is rigidly fixed, implying that there is configurationality at the clause level but not at the phrase level.

Over the years, there have been various suggestions concerning the history of the Torricelli languages. Authors have suggested a relationship with the Asli languages of Malaysia and with the East Bird's Head languages of western New Guinea. None of these claims has yet stood up to any serious investigation. The SVO order of the Torricelli languages, unusual in New Guinea, has been attributed to Austronesian contact (as has also been proposed for the similarly SVO languages of the Bird's Head), but it could just as easily be innate. The Torricelli languages are, indeed, not highlands languages, and there is no reason to suppose that SVO is not the original Torricelli order.

Totonacan Languages

C J MacKay and F R Trechsel, Ball State University, Muncie, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

The Totonacan languages are spoken in central Mexico in a region that includes parts of three states: southern Hidalgo, northern Puebla, and northwestern Veracruz (see Figures 1 and 2). Although proposals have sometimes been made to relate the Totonacan languages to Mayan, Mixe-Zoquean, and other languages in Mesoamerica (McQuown, 1942), these relationships have never been demonstrated. Today, the Totonacan language family is generally regarded as an 'isolate' in the classification of Mesoamerican languages (Suárez, 1983; Campbell, 1997). It is thought that speakers of these languages settled near the Gulf Coast around 800 A.D. Their original homeland is unknown; however, based on ethnohistorical sources and loanwords found in other Mesoamerican languages, it has been proposed that Totonacs may have founded Teotihuacan and moved to their current location following its collapse (Justeson *et al.*, 1985).

Totonacan Language Family

The Totonacan language family is made up of two branches: Totonac, consisting of four languages, with roughly 220 736 speakers, and Tepehua, consisting of three languages, with approximately 8252 speakers (INEGI–XII Censo General, 2000). Although the Totonac and Tepehua languages are mutually unintelligible today, they share a great deal of vocabulary and exhibit many structural similarities. These similarities indicate that the languages developed, historically, from a common ancestor, Proto-Totonacan. Figure 3 provides a simplified representation of the relationships of the various languages. As linguistic investigation proceeds, further groupings and subgroupings within the family will undoubtedly emerge.

As illustrated in Figure 3, the Totonac branch consists of four languages, referred to here as Misantla, Papantla, Sierra, and Northern:

Misantla Totonac, the southernmost variety, is spoken between the cities of Xalapa and Misantla in Veracruz. Towns where speakers may still be found include Yecuatla (192 speakers), San Marcos Atexquilapan (13), Landero y Coss (61), Chiconquiaco (56), and Jilotepec (11) (INEGI–XII Censo General, 2000). Misantla Totonac is moribund, with few native speakers remaining, all over the age of 45. The largest concentration of speakers is found in Yecuatla, but their number is dwindling rapidly. According to the Mexican Census, 486 individuals spoke Totonac in Yecuatla in 1980; in 2000, only

Figure 1 Mexico (adapted from a map drawn by Ashley Withers).

Figure 2 Totonacan language area (adapted from a map drawn by Ashley Withers).

Figure 3 Totonacan language family.

192 speakers remained (INEGI–Censo General, 1980, 2000). Data on Misantla Totonac come from Yecuatla and San Marcos Atexquilapan (MacKay, 1994, 1999; MacKay and Trechsel, 2003, in press).

Papantla Totonac is spoken by roughly 36 000 individuals in and around the city of Papantla, Veracruz. Children are still learning Papantla Totonac, but the language is being used less frequently within the communities. Data on Papantla Totonac come from El Escolín (Aschmann, 1973), Cerro del Carbón (Levy, 1987, 1990), and El Tajín (García Ramos, 2000).

Sierra Totonac is spoken by more than 100 000 people in the Sierra Norte de Puebla and nearby towns in Veracruz. The exact limits of Sierra Totonac and Northern Totonac are still being determined. Children continue to learn Sierra Totonac as their native language, and it is the main language used in many communities. Data on Sierra Totonac come from Zapotitlán de Méndez, Puebla (Aschmann and Wonderly, 1952; Aschmann, 1962), and Coatepec, Puebla (McQuown, 1990).

Northern Totonac is spoken by roughly 10 000 people in the region surrounding Xicotepec de Juárez, Puebla. It is unclear how many children are learning Northern Totonac; most speakers appear to be middle aged or older. Data on Northern Totonac come from Apapantilla, Puebla (Reid *et al.*, 1968; Reid and Bishop, 1974; Reid, 1991) and Patla and Chicontla, Puebla (Beck, 2004). Beck refers to the variety of Northern Totonac spoken in the latter two communities as Upper Necaxa Totonac.

The Tepehua branch of Totonacan consists of three languages, identified here as Tlachichilco, Pisaflores, and Huehuetla.

Tlachichilco Tepehua is spoken in Tlachichilco, Veracruz, and in the surrounding communities of Chintipán, Tierra Colorada, and Tecomajapa.

	Labial	Alveolar	Alveo-palatal	Palatal	Velar	Uvular	Glottal
Plosive	p	t			k	q	ʔ
Affricate		ts, tɬ[a]	tʃ				
Nasal	m	n					
Fricative		s, ɬ	ʃ				h
Approximant	w			y			
Lateral approximant		l					

[a] tɬ is found only in Sierra Totonac, Northern Totonac and Papantla Totonac.

Figure 4 Totonacan consonants.

According to the 2000 census, there are approximately 2463 speakers in these communities, many of whom are middle aged or older (Watters, 1988: 5). James K. Watters is the only linguist to have conducted research on Tlachichilco Tepehua. His publications include discussions of morphosyntax (1988), phonology (1987), verbal semantics (1996), and second-person laryngealization (1994). Although there is as yet no published lexicon or descriptive grammar of Tlachichilco Tepehua, it is the best documented of all the Tepehua languages.

Pisaflores Tepehua is spoken by roughly 2786 individuals in and around Pisaflores, Veracruz. Tepehua is the main language of this community and children are still learning it as their native language. Carolyn J. MacKay and Frank R. Trechsel have been conducting linguistic research in Pisaflores since 1997 and are working on a description of Pisaflores Tepehua.

Huehuetla Tepehua is spoken in and around the towns of Huehuetla, Hidalgo, and Mecapalapa, Puebla. There are approximately 1649 speakers of Huehuetla Tepehua, all of whom are at least middle aged. Publications on the language include a short sketch of sentence structure, a description of Tepehua numerals, and a preliminary description of verb inflection (Herzog, 1974). The Liga Bíblica Mundial del Hogar published the New Testament in Huehuetla Tepehua in 1976.

Totonacan Phonology

Totonacan languages exhibit three vowels, */a/*, */i/*, */u/*, and a length distinction, contrasting short and long vowels. Some languages, like Northern Totonac, have also developed phonemic */e/* and */o/* (Beck, 2004). Plain and laryngealized variants of both short and long vowels exist in all Totonacan languages. Whether this distinction is contrastive or predictable has not yet been determined for all varieties. However, all Totonacan languages employ laryngealization to mark second-person subjects.

(1) Misantla Totonac (MacKay, 1999: 156, 157)
[wíʃ kat̪sḭ́ḭ] 'you know X'
/wi̱ʃ kat̪sii/
[ʔṵ́t kat̪síi] 's/he knows X'
/ut kat̪sii/
[kin̪á̰n ká̰a̰yáa] 'we cut X'
/kin̪an ka̰a̰-yaa-wa/
[wi̱ʃín ká̰a̰yá̰a̰tat] 'y'all cut X'
/wi̱ʃin ka̰a̰-yaa-tat/

Figure 4 presents the consonants that are found in almost all Totonacan languages. In most Totonacan languages, glottal stop is contrastive only in word-final position. However, in Upper Necaxa Totonac, Pisaflores Tepehua, and Huehuetla Tepehua, /ʔ/ has replaced */q/* and therefore occurs in other positions as well.

Consonant alternations to mark degrees of size, force, and intensity have been described in Totonacan. This sound symbolism typically involves the sets of sounds s/ʃ/ɬ, k/q, and ts/tʃ with ɬ, q, and tʃ being the most intense (Bishop, 1984; Levy, 1987; MacKay, 1999; Beck, 2004).

(2) Misantla Totonac (MacKay, 1999: 114)
[tsṵtsṵ́] /tsũtsũ/ 's/he smokes'
[tʃṵ̃tʃṵ́] /tʃũtʃũ/ 's/he sucks'

(3) Papantla Totonac (Levy, 1987: 115)
sukũ 'small hole'
ɬukũ 'medium-sized hole'
ɬuqũ 'large hole'

Totonacan Morphology

Totonacan languages exploit a very complex and productive morphology, characterized by a large number of affixes, both prefixes and suffixes, that do most of the work of the grammar. Verbs and nominals are the major word classes.

Nominals

In some languages (e.g., Misantla Totonac and Sierra Totonac), adjectives and nouns do not differ in their inflectional morphology. In others, however (e.g., Papantla Totonac and Upper Necaxa Totonac), nouns and adjectives are distinct. Nominal inflectional morphology is relatively simple. Nominals are optionally marked for plurality, and in possessive constructions are also marked for person (and sometimes number) of possessors.

(4) Misantla Totonac (MacKay, 1999: 349)

[kíɲtʃík]	1POSS-house	'my house'
/kin-tʃik/		
[kíɲtʃikḭ́n]	1POSS-house-PL	'my houses'
/kin-tʃik-VVn/		
[kíɲtʃikã̰n]	1POSS-house-POSS.PL	'our house'
/kin-tʃik-kan̰/		
[kíɲtʃikḭ́ɲkã̰n]	1POSS-house-PL-POSS.PL	'our houses'
/kin-tʃik-VVn-kan̰/		

Numerals

The Totonacan numerical system, like many others in Mesoamerica, is vigesimal. In many of the Totonacan languages, the numerical system is being replaced by the Spanish one.

(5) Misantla Totonac (MacKay, 1999: 393, 394)

[puʃúmpuʃúmpuʃún]	'sixty (20 + 20 + 20)'
/puʃum-puʃum-puʃum/	
[tutún puʃún]	'sixty (3 × 20)'
/tutun puʃum/	

Body Part Prefixes

Body Part Prefixes occur on both nominal and verb stems, but are most productive on verbs. They usually denote either the body part affected by the action of the verb or a spatial relationship ('in front of,' 'behind,' 'beside,' 'above,' etc.).

(6) Misantla Totonac (MacKay, 1999: 230)
[míntaqa̰qa̰nṵ̰ut]
/min-ta-qa̰qa̰-nṵṵ-Vt/
2POSS-INCHOATIVE-ear rel.-inside-NOM
'your earring'

Verbal Inflection

Totonacan verbal morphology is characterized by a layering of derivational and inflectional affixes. Verbs may be inherently stative, intransitive, transitive, and, in some languages, ditransitive. In all languages, the verbal inflectional system distinguishes two aspectual categories (perfective and imperfective); two tense categories (past and nonpast); and two mood categories (realis and irrealis). In many, but not all, Totonacan languages, the inflectional system also marks categories of future tense and/or perfect aspect. The exact distribution of these latter categories in the family has yet to be determined.

In addition, in all Totonacan languages, verbal inflectional affixes mark categories of person and number of both subjects and objects. For the most part, inflectional affixes are transparent in the sense that they can be easily isolated and their semantic contribution is clear. In transitive sentences involving two nonthird-person arguments, however, certain contrasts are neutralized. In all languages except Sierra Totonac, combinations of a second-person subject and a first-person object, where either or both are plural, are expressed by means of reciprocal verbs with first person inclusive plural subjects. Sentences like the following, from Pisaflores Tepehua, are systematically ambiguous:

(7) Pisaflores Tepehua (MacKay and Trechsel, 2003: 295)
[kiláalá?tsi̱naaw]
/kin-laa-la?tsi̱n-yaa-wi/
1OBJ = RECIP-see.X-IMPERF-1SUBJ.PL
'You (sg.) see us,' 'You (pl.) see me,' 'You (pl.) see us'

A similar ambiguity emerges in sentences in which a first person subject acts on a second person object and, again, one or both are plural. In the Tepehua languages, these combinations are expressed by means of reciprocal verbs with first person exclusive plural subjects. The example in (8) is four-ways ambiguous:

(8) Pisaflores Tepehua (MacKay and Trechsel, 2003: 297)
[?i̱kláalá?tsĩnáaw]
/ik-laa-la?tsi̱n-yaa-wi/
1SUBJ-RECIP-see.X-IMPERF-1SUBJ.PL
'I see you (pl.),' 'We see you (sg.),' 'We see you (pl.),' 'We (excl.) see each other'

In contrast, the Totonac languages, with the exception of Sierra Totonac, use reciprocal verbs in 2SUBJ > 1OBJ contexts, but not in 1SUBJ > 2OBJ contexts. Nevertheless, all Totonac languages employ a single verb form to express combinations of first person subject and second person object where one or both are plural. Ambiguities of the sort illustrated in (7) and (8) are pervasive throughout the family.

Verbal Derivation

Totonacan languages exhibit a rich inventory of derivational affixes that affect the valence of both

transitive and instransitive verbs. The most productive are a causative affix, /maa-/ 'CAUS,' and several applicative affixes that license arguments interpreted as beneficiary, recipient/goal, instrumental, comitative, and others. In many languages, applicative affixes are the only means available for expressing arguments with these semantic roles.

(9) Misantla Totonac (MacKay, 1999: 274)
[ʔi̯klíilaq̯ɛnáan
/ik-lii-laq̯an-yaa-na
1SUBJ-INST-see X-IMPERF-2OBJ
kílíiláqtʃaqáatáayat]
kin-lii-laq = tʃaqaa-taaya-Vt/
1POSS-INST-eye rel.-upright-NOM
'I see you with my glasses'

On transitive verbs, causative and applicative affixes yield ditransitive verbs with two nonoblique objects. There is variation within the family concerning the treatment of these objects. At one extreme are languages like Misantla Totonac in which either or both of the objects may control overt object agreement. Sentences like (10) are systematically ambiguous in this language:

(10) Misantla Totonac (MacKay, 1999: 190)
[ʔi̯kláamakaʔi̯ʃki̯
/ik-laa-maka-i̯ʃki̯-wa
1SUBJ-3OBJ.PL-hand rel.-give X to Y-1SUBJ.PL
hɔ̃nlíbru]
hun-libru/
DET-book
'we handed them the book,' 'we handed him/her the books'

At the other extreme are languages like Papantla Totonac (Levy, 2000) in which only one of the two objects may control agreement.

(11) Papantla Totonac (Levy, 2000: 5)

ka:-ma:xi':-lh	lakcumaján	kin-qa'wasa
OBJ.PL-give-PFV	girls	1POSS-son

'I gave my son to the girls' / *'I gave the girls to my son'

Between these extremes are several intermediate types in which possibilities of double object marking are constrained by person and number features of the objects.

Totonacan Syntax

Word order in Totonacan languages is extremely flexible and almost any order is acceptable. In unmarked cases, word order is verb initial, and frequently VSO. Subjects may precede the verb for pragmatic effects associated with focus or topicalization.

Coordination and subordination are not explicitly marked and verbs in both clauses exhibit finite verbal morphology.

(12) Misantla Totonac (MacKay and Trechsel, in press)

[lakaa	ʔi̯knízpáa	hɔ̃n	tʃi̯ʃkúʔ
/lakaa	ik-nispaa	hun	tʃi̯ʃkuʔ

Tovar, Antonio (1911–1985)

N Lioce, Oostende, Belgium
P Swiggers, K. U. Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Acquainted with Basque and Valencian from early childhood on, Tovar was to develop wide-ranging linguistic interests. He studied in El Escorial, Valladolid (his native town), Madrid, Paris, and Berlin, taking degrees in law, history, archaeology, and classics. In 1941, he obtained his Ph.D. in Madrid. From 1942 until 1963, he held the chair of Latin in Salamanca, where he was *rector magnificus* from 1951 until 1956 (during 1948–1949, he taught at the University of Buenos Aires). In his youth an adherent of the *Falange*, Tovar had gradually distanced himself from the Franco regime. He was removed from his rectorship and from his chair in Salamanca, and he left Spain. He subsequently held university positions in Tucumán (1958–1959), Urbana-Champaign (1960–1961, 1963–1967), and Tübingen (1967–1979). After the political changes in Spain in the mid-1970s, he returned to his home country. He died in Madrid on December 14, 1985. Tovar was a member of the *Real Academia de la Lengua Española*, and he held honorary degrees from various universities.

Tovar's scientific output is exceptionally rich and variegated. As a classicist, he contributed to the historical grammar of Latin, to Greek history and archaeology, to the study of Plato, to epigraphy, etc. From Latin and Greek, he was led into the field of Indo-European comparative linguistics. He wrote on problems in the history (especially the history of the lexicon) of Celtic, Germanic, Slavic, and Italic. In 1977, he published a study on Krahe's theory of old-Indo-European river names. He also made significant contributions to the Romance field. In his study of lenition phenomena in Western Romance, he attributed voicing of single intervocalic stops to the (pre-)

Tovar, Antonio (1911–1985)

N Lioce, Oostende, Belgium
P Swiggers, K. U. Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Acquainted with Basque and Valencian from early childhood on, Tovar was to develop wide-ranging linguistic interests. He studied in El Escorial, Valladolid (his native town), Madrid, Paris, and Berlin, taking degrees in law, history, archaeology, and classics. In 1941, he obtained his Ph.D. in Madrid. From 1942 until 1963, he held the chair of Latin in Salamanca, where he was *rector magnificus* from 1951 until 1956 (during 1948–1949, he taught at the University of Buenos Aires). In his youth an adherent of the *Falange*, Tovar had gradually distanced himself from the Franco regime. He was removed from his rectorship and from his chair in Salamanca, and he left Spain. He subsequently held university positions in Tucumán (1958–1959), Urbana-Champaign (1960–1961, 1963–1967), and Tübingen (1967–1979). After the political changes in Spain in the mid-1970s, he returned to his home country. He died in Madrid on December 14, 1985. Tovar was a member of the *Real Academia de la Lengua Española*, and he held honorary degrees from various universities.

Tovar's scientific output is exceptionally rich and variegated. As a classicist, he contributed to the historical grammar of Latin, to Greek history and archaeology, to the study of Plato, to epigraphy, etc. From Latin and Greek, he was led into the field of Indo-European comparative linguistics. He wrote on problems in the history (especially the history of the lexicon) of Celtic, Germanic, Slavic, and Italic. In 1977, he published a study on Krahe's theory of old-Indo-European river names. He also made significant contributions to the Romance field. In his study of lenition phenomena in Western Romance, he attributed voicing of single intervocalic stops to the (pre-)

Celtic substratum. As a student of M. Gómez Moreno, Tovar also engaged in the study of the ancient, pre-Indo-European languages of the Iberian peninsula (and their later developments, e.g., into Celtiberian, the scientific study of which was initiated by Tovar in 1946) and in the study of Basque, to which he applied M. Swadesh's technique of lexicostatistics or glottochronology (yielding the controversial result of a closer affinity of Basque to the Berber languages than to Caucasian). Tovar's stay in South America resulted in a number of Americanist publications, the most important of which is the catalogue of South American Indian languages (1984), which contains useful bibliographical and typological information. Tovar also conducted fieldwork on South American languages, and he encouraged the study of pre-Columbian languages because of their relevance for a comprehensive approach to Hispanic culture.

A universal mind, Tovar also wrote on modern literature and music, and he participated in discussions concerning educational reform and the role of universities in the modern world.

Traditional Grammar

D Mulroy, University of Wisconsin-Milwaukee, Milwaukee, WI, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'traditional school grammar' was used by Fries in 1952 to distinguish grammar as commonly taught in the grade schools of the day from scientific linguistics. In this sense, 'traditional grammar' refers to the practical discipline that entered the educational tradition of the Western world as the first of the 'seven liberal arts,' a curriculum that has been traced to Plato's academy. An early Platonist, Crantor (4th century B.C.), is quoted as saying that students were not admitted there without having completed an *enkuklios paideia* or 'rounded education,' which consisted of grammar, rhetoric, logic, arithmetic, geometry, harmony, and astronomy (Stobaeus, 2.31.27; cp. 2.31.22, 28, 11, and Diogenes Laertius, 4.10). The Romans imitated this basic curriculum, introducing the term *artes liberales* or 'liberal arts' (Seneca, *Epistles* 88.23). Martianus Capella's *Marriage of Philology and Mercury*, a popular, allegorical work, perpetuated the prestige of the seven liberal arts during the Middle Ages.

Capella called the liberal arts 'divine bridesmaids,' exalted in one sense and humble in another: they were exalted because they were anchored in the innate, god-like capacities of the human mind and thus mastered as much by introspection as by empirical observation; humble, because they represented rudimentary abilities subservient to advanced studies. Grammar's position as the first of the liberal arts reflected the assumption that the ground rules of language are the first thing that an aspiring scholar in any field should master.

Aristotle distinguished between scientific and practical disciplines. A geometer views right angles in a scientific way; a carpenter, in a practical one (*Nichomachean ethics 1098a*). Traditional grammar is a practical discipline in the Aristotelian sense. At its heart is a rugged taxonomy of words: classifications that do not aspire to scientific exactitude but are useful in mastering languages. Aristotelian himself lay the foundation in *On interpretation (16a)* where he notes that a proposition, whose distinguishing characteristic is its association with truth or falsehood requires the union of a noun or verb. Herein lies the nucleus of traditional grammar, the insight that all complete sentences consist structurally of the union of a subject and a predicate.

The next step was taken by Dionysius Thrax, a Hellenistic scholar who studied at the library of Alexandria in the 2nd century B.C. and later taught grammar and literature on Rhodes. There he published

The term 'traditional school grammar' was used by Fries in 1952 to distinguish grammar as commonly taught in the grade schools of the day from scientific linguistics. In this sense, 'traditional grammar' refers to the practical discipline that entered the educational tradition of the Western world as the first of the 'seven liberal arts,' a curriculum that has been traced to Plato's academy. An early Platonist, Crantor (4th century B.C.), is quoted as saying that students were not admitted there without having completed an *enkuklios paideia* or 'rounded education,' which consisted of grammar, rhetoric, logic, arithmetic, geometry, harmony, and astronomy (Stobaeus, 2.31.27; cp. 2.31.22, 28, 11, and Diogenes Laertius, 4.10). The Romans imitated this basic curriculum, introducing the term *artes liberales* or 'liberal arts' (Seneca, *Epistles* 88.23). Martianus Capella's *Marriage of Philology and Mercury*, a popular, allegorical work, perpetuated the prestige of the seven liberal arts during the Middle Ages.

Capella called the liberal arts 'divine bridesmaids,' exalted in one sense and humble in another: they were exalted because they were anchored in the innate, god-like capacities of the human mind and thus mastered as much by introspection as by empirical observation; humble, because they represented rudimentary abilities subservient to advanced studies. Grammar's position as the first of the liberal arts reflected the assumption that the ground rules of language are the first thing that an aspiring scholar in any field should master.

Aristotle distinguished between scientific and practical disciplines. A geometer views right angles in a scientific way; a carpenter, in a practical one (*Nichomachean ethics 1098a*). Traditional grammar is a practical discipline in the Aristotelian sense. At its heart is a rugged taxonomy of words: classifications that do not aspire to scientific exactitude but are useful in mastering languages. Aristotelian himself lay the foundation in *On interpretation (16a)* where he notes that a proposition, whose distinguishing characteristic is its association with truth or falsehood requires the union of a noun or verb. Herein lies the nucleus of traditional grammar, the insight that all complete sentences consist structurally of the union of a subject and a predicate.

The next step was taken by Dionysius Thrax, a Hellenistic scholar who studied at the library of Alexandria in the 2nd century B.C. and later taught grammar and literature on Rhodes. There he published

treatises on language and literature. Of these, just one very brief one survives, *Techne Grammatikê* (The grammatical art). Despite its brevity, Dionysius' *Technê* was immensely influential in its classification of words into eight parts of speech. Before its appearance, the classification of most words was up in the air. Aristotle spoke of nouns, verbs, and everything else; more detailed systems were proposed without catching on. Dionysius' swept away the competition.

In its surviving form, Dionysius's work consists of 20 brief chapters, most no more than one brief paragraph in length. The first 10 chapters deal with the phonetic values of the letters of the Greek alphabet. Chapter 11 introduces the notion of the sentence and the parts of speech: "a sentence (logos) is an arrangement of words expressing a thought complete in itself (*dianoian autotelê*). There are eight parts of speech: noun, verb, participle, article, pronoun, preposition, adverb, conjunction." (Dionysius viewed adjectives as a subspecies of noun and participles as distinct from verbs.) The remaining chapters of his book give examples of each part of speech in order with some further subdivisions, e.g., the distinction between common and proper nouns.

Dionysius' doctrine of the eight parts of speech was adopted by Roman grammarians, especially Aelius Donatus, who flourished in Rome around 350 B.C. His pupils included St. Jerome, famous for translating the Bible into Latin. Donatus published literary commentaries, of which excerpts survive, and a two-part Latin grammar. The second part consists of a brief definition of the parts of speech in the form of a catechism:

> What are (the parts of speech)?
> Noun, pronoun, verb, adverb, participle, conjunction, preposition, interjection.
> What is a noun?
> A part of speech with a case ending and signifying a person or thing specifically or generically.

As this excerpt shows, articles, which Latin lacks, have been dropped and interjections have been raised in status from subspecies of adverb to their own part of speech. The only major difference between Donatus' list and modern ones is that the he continues to put nouns and adjectives into the same group while leaving participles in a separate category.

In the 5th century A.D. Priscian produced a much longer grammar, illustrating Donatus' definitions with extensive quotations from Greek and Latin literature. In the early Middle Ages, the study of Donatus and Priscian was synonymous with the study of grammar and early education in general.

Judging by some polemical writings of the day, the study of grammar declined in the High Middle Ages with the development of great European universities led by Paris. Aristotelian logic and its use in public disputations acquired great prestige, while the study of classical authors and the mastery of grammar that it required were neglected. In 1215, classical literature was completely absent from Paris's liberal arts curriculum, which was devoted entirely to logic. (Bursill-Hall, 1971: 24). The best known critic of this trend was John of Salisbury, a British scholar educated at Paris and elsewhere. He laments that at Paris the neglect of grammar produced "men who profess all the arts, liberal and mechanical, but who are ignorant of the very first one, without which it is futile to go on to attempt the others" (John of Salisbury, 1955: I.24, 71). In a similar vein, Henri d'Andeli composed a comical allegory, 'The Battle of the Seven Arts' in 1259. In it, Logic with its stronghold in Paris vanquishes grammar, but Andeli predicts that grammar will eventually be vindicated. "In every science," he concludes, "the 'master' who has not mastered the parts of speech is a mere child."

The restoration of grammar occurred as part of the humanist movement beginning in the 14th century. As Kristeller has made clear, the impact of Petrarch and the other 'humanists' was to restore prestige to the study of literary classics. An essential aspect of their program was the revitalization in primary education of the study of grammar. The grammar that dominated the schools in the 13th century was Alexander's *Doctrinale*. A lengthy work, written in metrical Latin in order to be memorized, its principal purpose was the acquisition of a large technical vocabulary, including Greek and Hebrew loan words, to assist students in disputations. In modern terms, it was aimed at acquiring proficiency in Latin through immersion.

As the humanist movement spread north from Italy, its exponents undertook the task of writing new Latin grammars. These were expositions of the parts of speech in Latin along the lines laid down by Donatus. An innovative feature of the humanist grammars was that they contained explanations and illustrations of grammar in the vernacular languages of the students for whom they were designed. Previously, it had been widely assumed that only classical languages had grammars. Hence though the primary goal of humanist grammars was to enable students to read and write correct, classical Latin, an unintended benefit was that the students gained a grammatical understanding of their mother tongues.

Erasmus was the person most responsible for bringing the humanist movement to England. One of Erasmus' British friends was John Colet, who endowed and re-established one of London's leading cathedral schools, St. Paul's, in 1509. Under his direction, St. Paul's became the first of the Renaissance

grammar schools in England, with a focus on the study of grammar and classical literature. Colet appointed William Lily as the first high master of St. Paul's. Among Lily's responsibilities was the compilation of a grammar to be used by his students. He composed a short work on the eight parts of speech, which was amended by Erasmus and published throughout Europe under the latter's name. Like all humanist grammars, Lily's explained Latin's parts of speech in terms of English, thus giving students incidental insights into their own language. In the 1540s, Lily's treatise on the parts of speech was combined with a work on morphology by Colet and published with a decree by Henry VIII prescribing its exclusive use in all British schools. Humanist reforms in British education bore fruit in the literary productions of the 16th and 17th centuries, including those of William Shakespeare, who like generations of British schoolboys was raised on Lily's grammar. Shakespeare is thought to have been an indifferent student of Latin, but in the judgment of Samuel Johnson, "he had Latin enough to grammaticize his English" (Baldwin, 1944: ii.668).

Traditional grammar, as epitomized by Lily, continued to be a major focus in English-speaking grade schools for at least three centuries after Shakespeare's time. Emphasis on it increased in the late 18th century and early 19th when the publication of authoritative dictionaries by Samuel Johnson and Noah Webster ignited interest in 'correct' or standard English, and the same period witnessed the first spate of books on proper grammar. In England, the most influential was Bishop Robert Lowth's *Short introduction to English grammar*, which went through 22 editions between its initial publication in 1762 and 1800. In the same period, a million copies of Lindley Murray's adaption of Lowth's work, *English grammar*, were sold in America. The prescriptions found in Lowth and Murray were based on the usage of the respected English authors. Their terminology and categories were adapted from classical Latin. It was in this period that English grammar began to be studied for its own sake.

It was also in the 18th century that Donatus' list of the parts of speech received its last major revision. In 1761, Priestley published an introduction to grammar in which he separated nouns and adjectives into separate categories while reclassing participles as forms of verbs. His classification has remained dominant.

Dionysius	*Donatus*	*Priestly*
Nouns (incl. Adjectives)	Nouns (incl.) Adjectives	Nouns
Verbs	Verbs	Verbs (incl. Participles)
Participles	Participles	******
Articles	******	Adjectives (incl. Articles)
Pronouns	Pronouns	Pronouns
Prepositions	Prepositions	Prepositions
Adverbs (incl. Interjections)	Adverbs	Adverbs
Conjunctions	Conjunctions	Conjunctions
******	Interjections	Interjections

Questions about the educational value of traditional grammar were raised by progressive educators early in the 20th century. At this time, educators were reconsidering the goals of education because of large numbers of grade-school and high-school students who were not destined to enter college. Since such students had no need or desire to read Latin and became fluent speakers of their mother tongues without formal instruction in grammar, progressives urged that the subject could be eliminated or greatly reduced in importance.

Skepticism about the educational value of grammar gained further ground later in the 20th century with the growth of interest in scientific linguists, according to whom, as descriptive scientists, there are no better or worse ways to speak, simply various dialects, all of which are governed by complex, largely subconscious rules. The 'prescriptivism' of 18th-century grammarians has often been criticized by modern linguists. In 1952, Fries equated 'traditional school grammar' with the practice of bleeding in medicine and urged educators to abandon it. His criticism was based on its prescriptivist tendencies and his belief that the traditional definition of the sentence and parts of speech were not scientifically valid. His position was endorsed in the United States by the National Council of Teachers of English in 1963. This led to reduced emphasis on grammar in American schools. Similar tendencies were at work in the United Kingdom.

In the 1990s, concern about students' verbal abilities in both countries led traditionalists to advocate a return to traditional grammar in education. In 1998, Britain's New Labour government made grammatical analysis the central point of its National Literacy Strategy, an integrated syllabus for teaching reading and writing in England's primary schools. In the United States, new academic standards adopted on a state-by-state basis typically mandated more attention to grammar. In neither country have the issues separating the traditional grammar's opponents and advocates been settled. The argument for traditional grammar is that it provides a structure that facilitates student achievement in reading, writing, and the study of foreign language. Opponents argue that its definitions are outmoded and that it fosters a prescriptivist attitude toward language that is unfounded and counterproductive.

More than 50 years ago, James Fisher and Robert Hinde (1949) documented the spread of a tradition of milk-bottle opening among British birds. Shortly thereafter, Satsue Mito discovered that several members of a troop of macaques living on Koshima Island in southern Japan would take dirt-covered sweet potatoes to a nearby stream and wash the dirt from them (Kawai, 1965). Geographical dialects in the songs of birds (*see* **Dialects in Birdsongs**) have long been a subject of discussion by ornithologists (Armstrong, 1963), and idiosyncratic feeding behaviors in various populations of Norway rats have been reported for many decades (for a review, see Galef, 2003b). Such observations provided the first evidence that members of a single species living in different areas exhibit differences in their behavioral repertoires that are not readily explained in terms of differences in either their genotypes or their ecological circumstances. The evidence, fragmentary though it was, led to a resurgence of interest in laboratory studies of the behavioral processes supporting social learning in animals as well as extraordinary efforts to describe differences in the behavior of geographically distinct populations of free-living primates.

Evidence from the field of differences in the behavior of geographically distinct populations within a species is now overwhelming not only in the great apes and other mammals, but in fish and birds as well (e.g., Box and Gibson, 1999; Fragaszy and Perry, 2003). For example, chimpanzees at Gombe National Park in east Africa hold a long stick in one hand and use the other to wipe ants from the probe and transfer the ants to their mouths. Chimps living in the Tai Forest in west Africa use a short stick to collect ants and their mouths to remove ants from the stick (McGrew, 1992; Whiten *et al.*, 1999). Studies of orangutan populations scattered across Southeast Asia have revealed similar differences in behavior

Such observations provided the first evidence that members of a single species living in different areas exhibit differences in their behavioral repertoires that are not readily explained in terms of differences in either their genotypes or their ecological circumstances. The evidence, fragmentary though it was, led to a resurgence of interest in laboratory studies of the behavioral processes supporting social learning in animals as well as extraordinary efforts to describe differences in the behavior of geographically distinct populations of free-living primates.

Evidence from the field of differences in the behavior of geographically distinct populations within a species is now overwhelming not only in the great apes and other mammals, but in fish and birds as well (e.g., Box and Gibson, 1999; Fragaszy and Perry, 2003). For example, chimpanzees at Gombe National Park in east Africa hold a long stick in one hand and use the other to wipe ants from the probe and transfer the ants to their mouths. Chimps living in the Tai Forest in west Africa use a short stick to collect ants and their mouths to remove ants from the stick (McGrew, 1992; Whiten *et al.*, 1999). Studies of orangutan populations scattered across Southeast Asia have revealed similar differences in behavior

among geographically distinct populations (Van Schaik *et al*., 2003). Important articles have appeared in the scientific literature using the term 'culture' to describe the local-specific behavioral repertoires of populations of chimpanzees and orangutans (Whiten *et al*., 1999; Van Schaik *et al*., 2003), suggesting fundamental similarities in the traditions of humans and great apes.

There is disagreement as to the appropriateness of such a usage. Some argue that although human culture and animal traditions share certain features, until we have a better understanding of how behavior is transmitted in both animals and humans, it is premature to assume that they are equivalent (Galef, 1992). Others feel that the specific mechanisms involved in the diffusion of behaviors through populations can be ignored when discussing traditions or culture because the evolutionary consequence of social learning, however it occurs, is always the same: behavior is transmitted (de Waal and Tyack, 2003).

From the perspective of those interested in language and linguistics, the differences between the traditions of animals and those of humans appear profound indeed. Although there has been relatively little study of the way in which humans acquire traditional patterns of behavior, many aspects of human culture, especially those involving the acquisition of complex skills, appear to depend on language, on teaching, and on imitation for their propagation.

Although apes have the capacity to manipulate a symbolic system invented and given to them by humans and to communicate with it (*see* **Cognitive Basis for Language Evolution in Non-human Primates**), there is no evidence that free-living apes communicate in a similar way. Anecdotal reports suggest that chimpanzees may engage in activities that can be interpreted as deliberate tuition of their young. However, teaching, as we know it in humans, appears to play a limited role, if any, in the development of the behavioral repertoires of apes. Chimpanzees and orangutans probably can imitate to some extent, but the contribution of imitation of others to the development of behavior of free-living animals is not known. If even our closest phylogenetic relatives rarely transmit behavior as we do, how is the existence of traditions in animals to be understood?

Like humans, nonhuman animals provide conspecifics with whom they share an environment with information useful in determining which of many possible behaviors is likely to be successful. In some cases, the traditions of animals are shaped and maintained by signals (behaviors evolved for the purpose of communication) emitted by one animal that influence the behavior of another. For example, male cowbirds from different geographical areas sing different variants of male-cowbird song, and these 'song dialects' are maintained by differences in the response of females from different areas to the songs that males produce. Although male cowbirds normally sing all of the various songs in their repertoires without repetition, after a female cowbird gives a wing stroke display in response to a male's song, he repeats that song several times in succession. During the breeding season, males tend to produce songs that previously caused females to give wing stroke displays and thus increase their access to females (West and King, 1988). Other contributors to this encyclopedia have discussed, either in detail or in passing (*see* **Animal Communication: Overview**; **Animal Communication: Vocal Learning**; **Cognitive Basis for Language Evolution in Non-human Primates**; **Communication in Marine Mammals**; **Dialects in Birdsongs**), traditions that similarly involve signals shaped by natural selection for the purpose of communication. I focus here on 'communications' between animals that do not involve signals that evolved for communicative purposes. Animals can learn from others not because those others actively provide information, but because stimuli that others emit as byproducts of activities necessary for their own maintenance incidentally direct the behavior of recipients in profitable directions (e.g., King, 1994). For example, the rasping sounds that an agouti makes as it gnaws on a nut carry for many tens of meters through the forests of Central America, attracting both other agouti and the occasional predator to a promising feeding site. A vulture descending to feed from a carcass lying on the Serengeti Plain attracts both others of its kind and competing species to a recent kill. It does not seem reasonable to suppose that, in such cases, individuals that have discovered a food source emit signals to announce their finds. Still, the feeding behavior of one agouti or vulture provides an unambiguous cue to those sufficiently alert to detect and exploit it.

Sometimes the behavior of one animal results in residual changes in the environment that affect the behavior of conspecifics. As a Norway rat moves about its home range, it creates paths through the undergrowth that influence the behavior of those that come after. As it feeds, it deposits residual olfactory cues in the saliva it leaves on its food and in the feces it voids in the location where it eats. Such residual signs are attractive to other rats and strongly bias their choice of feeding site (Galef, 2003b).

Sometimes, the effects of environmental modification of the behavioral development of others are quite sophisticated. For example, the pine forests of Israel are inhabited by colonies of roof rats that live on a diet of pine seeds and water. Laboratory observation

of roof rats captured either in pine forest or elsewhere in Israel reveals that although all of the former animals are able to extract pine seeds from cones in a way that provides more energy than it consumes, few rats captured outside the pine forest can do so. The efficient method of harvesting pine seeds takes advantage of the architecture of cones and involves starting at the base of a cone and removing, in succession, the spiral of scales that run from the base of a cone to its apex. Regardless of genetic background, rat pups reared by dams that open pinecones in their presence usually develop the efficient technique, whereas few pups reared by dams not given access to pinecones do so. Experience of young rats in completing the removal of scales from cones started in the right way by an adult rat (or by a human stripping scales from the base of a cone in imitation of a proficient adult) allowed most of them to acquire the efficient technique (Terkel, 1995). Clearly, socially produced residual changes in the environment provide the necessary substrate for diffusion of behavior through rat populations.

In discussion of the development of behavioral traditions in members of our own species, the role of information acquired as a result of observation of the activities of others as they go about behaviors necessary for self-maintenance is easily overlooked. We talk, we teach, we confer, we advertise. It is easy to forget that we also act and that our activities provide useful, often unambiguous messages for others, modeling behaviors that are likely to be rewarded in a shared environment. Extraction of information from the life-sustaining activities of others and the residues such activities leave in the environment, rather than from signals that have an explicitly communicative function, can prove useful, even for humans.

There has been considerable discussion among behavioral ecologists as to whether signals passing from one animal to another provide a recipient with honest information or are designed to manipulate the behavior of a signal recipient to the sender's advantage (*see* **Animal Communication: Deception and Honest Signaling**). Information extracted from observation of the life-sustaining activities of others is less likely to misinform than information extracted from signals evolved for communicative purposes. No animals other than humans, and perhaps chimpanzees, have been shown to modify behaviors involved in their own maintenance so as to mislead others. Consequently, information extracted from signs and cues emitted by others, rather than information extracted from signals that evolved for purposes of communication, is likely to be particularly useful.

Information extracted from the behavior of others can both introduce novelty into behavioral repertoires and lead to homogeneity in the behavior of members of a population (Galef, 2003a). However, like other elements in the behavioral repertoires of individuals, behaviors acquired by extracting information from signs or cues produced by others are rewarded or punished during subsequent interaction with the physical and social environments. Consequently, socially acquired behaviors will increase or decrease in frequency of expression in a population as a function of their costs and benefits relative to alternative behaviors in the repertoires of population members. There is no reason to believe that there is anything special about behaviors that are acquired socially. Like behaviors acquired as the result of individual experience, continued expression of a socially learned behavior depends on the reward it produces relative to alternative related behaviors in an individual's repertoire. Still, information extracted from others as they go about the mundane tasks necessary for self-maintenance, like the signals that other contributors to this encyclopedia discuss, can bias the development of behavioral repertoires of nonverbal species (Boyd and Richerson, 1985).

Trager, George L. (1906–1992)

A Kaye, California State University, Fullerton, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Trager was born on March 22, 1906 in Newark, NJ, and died on August 31, 1992 in Pasadena, CA. He is well-known for his contributions to structural linguistics, phonetics, American Indian languages, Romance philology, and Slavic and Germanic linguistics.

The young Trager, whose parents emigrated from Russia via Germany, grew up speaking Russian and German at home, and English in his Newark neighborhood and in school. An excellent student in the public schools of Newark, he was awarded a full state scholarship to attend Rutgers University in 1922. Although his first declared major was chemistry, he graduated in 1926 with a B. Litt. in Romance languages. He received both his A.M. (1929) and Ph.D. (1932) in Romance Philology from Columbia University. His dissertation (Trager, 1932) was supervised by H. R. Muller, with L. H. Gray serving on his committee. Although his forte was in Romance, he was also competent in Slavic (see Trager, 1933, 1942). Two classic studies deal with French morphology (Trager, 1944, 1955), a particular strength of his, and he taught French at Brown University and Columbia University.

Trager was a Research Associate of the International Auxiliary Language Association from 1931–1934. He taught every foreign language offered at Adams State College in Alamosa, CO, from 1934–1936. It was during this period that he began his lifelong fieldwork on Taos, a Tanoan language spoken about 100 miles from Alamosa. He was a postdoctoral scholar at Yale University from 1936–1938, and a research fellow there from 1936–1941. He was Lecturer in Phonetics for 1937–1938 (see Trager and Bloch, 1940; Trager, 1950a, 1964, e.g., for his special expertise in that subject). He later served there as Assistant Professor of Slavic Languages (1942–44). During the Yale years, he came in contact with numerous superstars of the structuralist era: E. Sapir, M. Swadesh, C. Osgood, F. Edgerton, E. H. Sturtevant, M. B. Emeneau, C. F. Hockett, B. L. Whorf, and also L. Bloomfield. He collaborated with Whorf, B. Bloch, and with others (e.g., H. L. Smith, Jr.) in a long and distinguished career.

Trager was Chief Linguistics Secretary for the U.S. Board of Geographical Names from 1944–1946. He then was Professor of Linguistics at the University of Oklahoma, Norman, from 1946–1948, followed by a stint as Professor of Linguistics at the Foreign Service Institute from 1948–1953. He also served as Director of Linguistic Research at the Institute of Languages and Linguistics, Georgetown University from 1950–1953, and was Visiting Professor there for 1954–1955. After Georgetown, he became the Assistant Director of the Human Relations Area Files, Washington Bureau, American University, for 1955–1956. He became Professor of Anthropology and Linguistics, University of Buffalo, 1956–1957, and

Galef B G Jr (2003a). 'Social learning: Promoter or inhibitor of innovation.' In Reader S & Laland K N (eds.) *Animal innovation*. Cambridge: Cambridge University Press. 137–155.

Trager, George L. (1906–1992)

A Kaye, California State University, Fullerton, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Trager was born on March 22, 1906 in Newark, NJ, and died on August 31, 1992 in Pasadena, CA. He is well-known for his contributions to structural linguistics, phonetics, American Indian languages, Romance philology, and Slavic and Germanic linguistics.

The young Trager, whose parents emigrated from Russia via Germany, grew up speaking Russian and German at home, and English in his Newark neighborhood and in school. An excellent student in the public schools of Newark, he was awarded a full state scholarship to attend Rutgers University in 1922. Although his first declared major was chemistry, he graduated in 1926 with a B. Litt. in Romance languages. He received both his A.M. (1929) and Ph.D. (1932) in Romance Philology from Columbia University. His dissertation (Trager, 1932) was supervised by H. R. Muller, with L. H. Gray serving on his committee. Although his forte was in Romance, he was also competent in Slavic (see Trager, 1933, 1942). Two classic studies deal with French morphology (Trager, 1944, 1955), a particular strength of his, and he taught French at Brown University and Columbia University.

Trager was a Research Associate of the International Auxiliary Language Association from 1931–1934. He taught every foreign language offered at Adams State College in Alamosa, CO, from 1934–1936. It was during this period that he began his lifelong fieldwork on Taos, a Tanoan language spoken about 100 miles from Alamosa. He was a postdoctoral scholar at Yale University from 1936–1938, and a research fellow there from 1936–1941. He was Lecturer in Phonetics for 1937–1938 (see Trager and Bloch, 1940; Trager, 1950a, 1964, e.g., for his special expertise in that subject). He later served there as Assistant Professor of Slavic Languages (1942–44). During the Yale years, he came in contact with numerous superstars of the structuralist era: E. Sapir, M. Swadesh, C. Osgood, F. Edgerton, E. H. Sturtevant, M. B. Emeneau, C. F. Hockett, B. L. Whorf, and also L. Bloomfield. He collaborated with Whorf, B. Bloch, and with others (e.g., H. L. Smith, Jr.) in a long and distinguished career.

Trager was Chief Linguistics Secretary for the U.S. Board of Geographical Names from 1944–1946. He then was Professor of Linguistics at the University of Oklahoma, Norman, from 1946–1948, followed by a stint as Professor of Linguistics at the Foreign Service Institute from 1948–1953. He also served as Director of Linguistic Research at the Institute of Languages and Linguistics, Georgetown University from 1950–1953, and was Visiting Professor there for 1954–1955. After Georgetown, he became the Assistant Director of the Human Relations Area Files, Washington Bureau, American University, for 1955–1956. He became Professor of Anthropology and Linguistics, University of Buffalo, 1956–1957, and

Chair of Modern Languages, 1956–58. Moving to Dallas, he became Professor of Anthropology at Southern Methodist University from 1967–1971, becoming Emeritus in 1971. After retiring in Dallas, he secured another position at Northern Illinois University, De Kalb, in 1971 as Professor of Anthropology.

Trager's accomplishments include the following: Ford Foundation Visiting Lecturer, School of Applied Linguistics, University of Edinburgh, 1969; Guggenheim Fellow, 1941–1942, for the study of Slovene immigrants in PA; National Science Foundation (NSF) Research Grantee, Taos Pueblo, NM, 1959–1960; Fellow, Center for Advanced Study in the Behavioral Sciences, Stanford, CA, 1962–1963; NSF Research Grantee, 1964–1967; Fellow, American Anthropological Association; Fellow, American Academy of Arts and Sciences; President, Linguistic Society of America, 1960. Trager (1963) was his Presidential address, which B. Bloch, as editor of *Language*, refused to publish, presumably for its lack of scholarly content.

During his vibrant years in the 1940s, Trager was well-known for cofounding (along with C. F. Hockett) an informal linguistics journal, *Studies in Linguistics*. Trager was editor; M. Joos was the publisher until 1947. Thereafter, the whole enterprise rested on Trager's shoulders. Many of Trager's works were published in this series (e.g., 1949, 1958, 1963). *Studies in Linguistics* ended publication with Vol. 25 (1975), and Fickett (1975) was its last *Occasional Paper*.

Trager's fame as a structuralist rests primarily on his collaborative efforts: Trager and Bloch (1940), Trager and Bloch (1942), Trager and Rice (1950), Trager and Smith (1951), and Trager and Hall (1953). The phonetic chart of Trager and Bloch (1942: 22), more detailed than the standard IPA chart, became legendary for its completeness. Trager and Smith (1951) presented many classical statements on complex nuclei, internal open and terminal juncture, superfixes, intonation patterns, and metalinguistics. Trager and Harben (1958) demonstrated Trager's expertise in North American Indian linguistics.

Trager's (1972) textbook appeared in the Chandler Publications series in Anthropology and Sociology edited by L. Broom. The nine-chapter volume was unusual for its time and probably is also unusual today in that it devoted considerable space to grammatology – a special interest of his for a long time (1972; 179–310). Here, he made the bold pronouncement that "the ANTHROPOLOGY of spelling reform is as yet an almost completely unexplored field" (1972: 310). It should be noted that Trager considered the Semitic alphabets to be real alphabets – not syllabaries or the like, with the exception of Ethiopic (1972: 268–275).

Trager (1971) contains an annotated bibliography of Trager's publications through 1970, while Smith (1972) was the Trager *festschrift*. Manaster-Ramer (1994) called attention to the fact that Trager's publications on French (especially 1944 and 1955) were among the earliest arguing for abstractness in phonology. Manaster-Ramer (1994) also noted that Trager's analysis of ergativity in Taos "elegantly account[s] for the formal identity of intransitive subjects with objects." Of interest to the history of linguistics, mention should be made of Hockett (1993), which presented many important details on Trager's life and oeuvre, also touching on his personal (and often tragic) circumstances and relationships with other linguists.

Trans New Guinea Languages

A Pawley, Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Trans New Guinea Family

Comprising upward of 400 languages, Trans New Guinea (TNG) is the third largest family in the world in number of languages, behind Austronesian and Niger-Congo and ahead of Indo-European. TNG is the predominant family on the large island of New Guinea, a region of spectacular linguistic diversity that contains some 18 families that are not demonstrably related (*see* **Papuan Languages** and **Austronesian Languages: Overview**). TNG languages are spoken continuously along the 2000-km mountain chain that runs along the center of New Guinea as far west as the Bird's Head, and they also are used in several parts of the lowlands. At least a dozen TNG languages are also present on Timor, Alor, and Pantar Islands in East Nusantara.

About 3 million people speak TNG languages. Yet, most of the languages have fewer than 5000 speakers. Their small size reflects the difficult terrain of New Guinea in combination with extreme political fragmentation; peoples were traditionally subsistence farmers or foragers, and until colonial times political groups seldom exceeded a few hundred people. The largest TNG language communities are Enga (about 200 000) and Medlpa (Melpa; 150 000) in the highlands of Papua New Guinea, and Western Dani (150 000) and Lower Grand Valley Dani (130 000) in the highlands of West Papua (Irian Jaya).

Until the late 19th century, the TNG languages of New Guinea were completely unknown to linguists, and most remained unrecorded until after World War II. Since then, linguists from various parts of the world have done descriptive and comparative work on TNG languages. Although most are still only documented (at best) by grammatical sketches and word lists, there are quite detailed published grammatical descriptions of perhaps 50 to 70 TNG languages. Reasonably good dictionaries exist for about 20 TNG languages. Excellent introductory overviews are given in Foley (1986, 2000). The atlas of Wurm and Hattori (1981–83) contains detailed maps, and Carrington's work (1996) is a near-exhaustive bibliography. Languages for which there are good grammars include Korafe of the Binandere group (Farr, 1999), Grand Valley Dani (Bromley, 1981), Hua (a dialect of Yagaria) of the Gorokan group (Haiman, 1980), and Eipo (Eipomek) of the Mek group (Heeschen, 1998).

History of the Trans New Guinea Hypothesis

The hypothesis that there is a large TNG family was proposed about 1970 by linguists at the Australian National University, mainly on the basis of typological resemblances and a handful of widespread putative cognates (McElhanon and Voorhoeve, 1970: Wurm, 1975). However, critics argued that the hypothesis was based on unreliable methods and that the evidence was unconvincing. Percentages of resemblant basic vocabulary forms shared by languages belonging to distant branches of TNG are very low, in the range of 3–7%, and in a region where there has been extensive lexical diffusion for millennia, this level of agreement could be due to borrowing and chance. Recently, linguists have applied more classical comparative methods and have found evidence that strongly supports a modified version of the TNG hypothesis (Pawley, 1995: Ross, 1995; Pawley, 1998, 2001, in press; Ross, in press).

The Trans New Guinea Family

Comprising upward of 400 languages, Trans New Guinea (TNG) is the third largest family in the world in number of languages, behind Austronesian and Niger-Congo and ahead of Indo-European. TNG is the predominant family on the large island of New Guinea, a region of spectacular linguistic diversity that contains some 18 families that are not demonstrably related (*see* **Papuan Languages** and **Austronesian Languages: Overview**). TNG languages are spoken continuously along the 2000-km mountain chain that runs along the center of New Guinea as far west as the Bird's Head, and they also are used in several parts of the lowlands. At least a dozen TNG languages are also present on Timor, Alor, and Pantar Islands in East Nusantara.

About 3 million people speak TNG languages. Yet, most of the languages have fewer than 5000 speakers. Their small size reflects the difficult terrain of New Guinea in combination with extreme political fragmentation; peoples were traditionally subsistence farmers or foragers, and until colonial times political groups seldom exceeded a few hundred people. The largest TNG language communities are Enga (about 200 000) and Medlpa (Melpa; 150 000) in the highlands of Papua New Guinea, and Western Dani (150 000) and Lower Grand Valley Dani (130 000) in the highlands of West Papua (Irian Jaya).

Until the late 19th century, the TNG languages of New Guinea were completely unknown to linguists, and most remained unrecorded until after World War II. Since then, linguists from various parts of the world have done descriptive and comparative work on TNG languages. Although most are still only documented (at best) by grammatical sketches and word lists, there are quite detailed published grammatical descriptions of perhaps 50 to 70 TNG languages. Reasonably good dictionaries exist for about 20 TNG languages. Excellent introductory overviews are given in Foley (1986, 2000). The atlas of Wurm and Hattori (1981–83) contains detailed maps, and Carrington's work (1996) is a near-exhaustive bibliography. Languages for which there are good grammars include Korafe of the Binandere group (Farr, 1999), Grand Valley Dani (Bromley, 1981), Hua (a dialect of Yagaria) of the Gorokan group (Haiman, 1980), and Eipo (Eipomek) of the Mek group (Heeschen, 1998).

History of the Trans New Guinea Hypothesis

The hypothesis that there is a large TNG family was proposed about 1970 by linguists at the Australian National University, mainly on the basis of typological resemblances and a handful of widespread putative cognates (McElhanon and Voorhoeve, 1970: Wurm, 1975). However, critics argued that the hypothesis was based on unreliable methods and that the evidence was unconvincing. Percentages of resemblant basic vocabulary forms shared by languages belonging to distant branches of TNG are very low, in the range of 3–7%, and in a region where there has been extensive lexical diffusion for millennia, this level of agreement could be due to borrowing and chance. Recently, linguists have applied more classical comparative methods and have found evidence that strongly supports a modified version of the TNG hypothesis (Pawley, 1995: Ross, 1995; Pawley, 1998, 2001, in press; Ross, in press).

Table 1 Proto TNG free pronouns

	1st person	*2nd person*	*3rd person*
sing.	na	ŋga	[y]a, ua
pl. (i-agrade)	ni	ŋgi, ki	i
(u-grade)	nu		
pl.	nja		

Table 2 Some cognate sets of the Trans New Guinea family

	'breast'	*'eat'*	*'louse'*	*'name'*
Proto TNG	*amu	*na-	*niman	*imbi
Asmat (Irian Jaya)		na-		yipi
Kiwai (SW coast, PNG)	amo		nimo	
Kewa (W. Highlands, PNG)		na-		ibi
Kuman (C. Highlands, PNG)	aemu		numan	
Kube (Morobe, PNG)	namu	ne-	imiŋ	
Katiati (Madang Province, PNG)	ama		ñima	nimbi
Aomie (Central Province, PNG)	ame		ume	ihe

The main grounds for considering TNG to be a language family are (1) systematic form-meaning correspondences in the independent personal pronouns, permitting reconstruction of virtually a complete paradigm (Table 1); (2) some 200 putative cognate sets (nearly from 'basic vocabulary') being represented in two or more major subgroups (Table 2); (3) a body of regular sound correspondences for a small sample of languages belonging to eight different subgroups, which has allowed a good part of the Proto TNG sound system to be reconstructed (Table 3); and (4) resemblances in certain other grammatical paradigms, chiefly the form of verbal suffixes marking person-number of subject. In addition, the distribution of certain striking structural features, such as switch-reference morphology on verbs, has been shown to correlate rather closely with the distribution of TNG languages.

TNG seems to have had a simple syllable structure, with syllables of the shape (C)V and (word-finally) CVC.

Subgroups of Trans New Guinea

More than 30 subgroups are recognized that have not been assigned to any larger grouping within Trans New Guinea. Much of the evidence for these groups is based on innovations in the personal pronouns (Ross, in press). The following is a selection of the more important subgroups.

Madang (Madang-Adelbert Range) is by far the largest well-defined subgroup of TNG, with about

Table 3 Proto TNG segmental phonemes (Minimal set)

	Bilabial	*Apical*	*Palatal*	*Velar*
Consonants				
oral obstruents	p	t s		k
prenasalized obstruents	mb	nd	nj	ŋg
nasals	m	n		ŋ

Vowels	front	central	back	
high	i		u	
mid	e		o	
low		a		

100 members (*see* **Madang Languages**). It occupies the central two-thirds of Madang Province from the coast to the Bismark and Schrader Ranges. Huon-Finisterre contains about 70 languages spoken on the Huon Peninsula and in the Finisterre and Saruwagi Ranges in Morobe and Madang Provinces. Chimbu-Wahgi (Chimbu) is centered east and south of Mt. Hagen, in the Wahgi, Nebilyer, and Kaugel Valleys and extends north of the Sepik-Wahgi Divide into the Jimi Valley. It contains perhaps 12 languages, although the situation is complicated by extensive dialect chaining. The best-known members are probably Kuman (Chimbu), Middle Wahgi, Sinasina, and Medlpa (Melpa). Engan is a well-defined group consisting of several languages spoken over a wide area to the west of Mt. Hagen. There is a northern subgroup that includes Enga, Ipili, Iniai (Bisorio), and Lembena and a southern subgroup that includes Sau (Samberigi), Huli, Mendi (Angal), and Kewa.

The Kainantu and Goroka groups occupy contiguous parts of Eastern Highlands Province. Each consists of a half a dozen or so languages, some with diverse dialects. Together they probably form a single higher-order larger subgroup, Kainantu-Goroka. The Angan group of about 12 languages occupies considerable areas of Morobe and Guilf Provinces and extends into the Eastern Highlands province. Southeast New Guinea contains the Dagan, Mailuan, Yareba, Manubaran, Kwalean, and Koiari groups, which all replace Proto TNG **ŋgi* '2 PL' by **ya*, as well as the Binandere and Goilalan groups.

The Ok group comprises about about 10 languages spoken in the central ranges around the West Papua-Papua New Guinea border, including the Star Mountains, and the Thurnwald and Victor Emmanual Ranges. The Awyu-Dumut and Asmat-Kamoro groups occupy the lowlands to the southwest of this area, in West Papua. The Dani languages spoken in and around the Baliem Valley and the Wissel Lakes languages seem to belong together in a Western New Guinea group. The West Bomberai and Timor-Alor-Pantar groups

share two probable innovations in pronouns, which suggests that together they may form a West Trans New Guinea group (Figure 1).

Where and When was Proto TNG Spoken?

The largest concentration of established high-order subgroups of TNG lies in the central highlands of Papua New Guinea between the Strickland River and Eastern Highlands. It is safe to say that this was a very early area of TNG expansion and that initial dispersal was mainly along the central cordillera. If we take conventional estimates for the breakup of Indo-European (at least 6000 years ago) and Austronesian (about 5000 years ago) as yardsticks, a date of between 8000 and 12 000 years ago for the breakup of TNG is reasonable, given that lexicostatistical diversity within TNG is far greater than in either Indo-European or Austronesian. It is noteworthy that dates of about 10 000 years ago have been established for early agriculture, probably based on taro and bananas, in the Upper Wahgi Valley (Denham *et al.*, 2003). It may have been their use of agriculture that enabled speakers of TNG languages to establish permanent settlements along the central highlands of New Guinea as the climate warmed after the last Ice Age.

Structural Characteristics of TNG Languages

Phonology

Many TNG languages have sound systems similar to that posited for Proto TNG, with syllables of the shape (C)V and (word-finally) CVC, five vowels, and series of nasals, oral, and pre-nasalized (or voiceless and voiced) obstruents with contrasts at bilabial, apical, and velar (and sometimes palatal) positions. A number of languages in the central highlands have a contrast between dental, alveo-palatal, and velar laterals, or between resonant and fricative palatals. [t] and [r] are often allophones of the same phoneme. Many TNG languages have word tone or pitch accent (Donohue, 1997).

Grammar and Semantics

The preferred order of constituents in verbal clauses is SOV, but OVS often occurs as a marked structure. Adpositions follow the verb, whereas determiners and possessors follow the noun. Case marking is generally absent or little developed. Most languages organize pronominal affixes to show a nominative-accusative (or dative) contrast. No language is known to have a full ergative-absolutive alignment for verb pronominals.

Generally, a verb root cannot be used as a noun without derivational morphology or vice versa. In some languages verb roots are a small closed class, with between 50 and 150 members. The densest concentration of such languages seems to be in the Chimbu-Wahgi and Kalam-Kobon subgroups. Common nouns are an open class with many subclasses. Minor classes include adjectives, adverbs, and (see below) verbal adjuncts.

TNG languages typically have fairly simple systems of independent pronouns, in some cases distinguishing three persons but with no number contrasts. More complex pronoun systems are constructed by adding number markers for dual and plural. However, there is often a discrepancy between the kinds of distinctions made in independent pronouns and in verbal affixes. For example, Kuman of the Chimbu-Wahgi family has only four independent pronouns – first person singular, first person plural, second person, and third person – but in verbal morphology Kuman makes nine contrasts for the subject: three persons each with singular, dual, and plural.

Morphology is chiefly suffixal. In most languages, nouns carry little morphology. Kinship terms and sometimes part terms often require affixed possessive pronouns. A few languages mark gender contrasts. A good many TNG languages use existential verbs, such as 'stand', 'sit', 'lie' and sometimes, other verbs like 'hang', 'carry' and 'come', as quasi-classifiers of nouns (Lang, 1975), with nouns selecting a verb according to their shape, posture, size, and composition. However, the choice of verb has some flexibility relative to the situation of the referent. Nouns are usually not inflected for number. Certain generic categories are typically expressed by N + N (and occasionally N + N + N) compounds denoting the most salient members of a class (e.g., often 'people' is 'woman-man', 'children' is 'girl-boy', and 'ancestors' is 'grandmother-grandfather'.

Most TNG languages distinguish two types of inflected verb, often called 'final' and 'medial.' Final verbs head the final clause in a sentence and carry suffixes marking absolute tense-aspect-mood and person-number of subject. Medial verbs head nonfinal coordinate-dependent clauses and carry suffixes marking (1) whether the event denoted by the medial verb occurs prior to or simultaneous with that of the final verb and (2) 'switch reference' (i.e., whether that verb has the same subject or topic as the next clause; Roberts (1997) surveys the several kinds of switch-reference systems.) In many languages, transitive verbs also carry a pronominal prefix or proclitic marking object agreement. Some languages have

Figure 1 Location of the main subgroups of the Trans New Guinea family.

causative and applicative affixes that add arguments to the verb. Several Highlands subgroups carry evidential suffixes, indicating whether the clause denotes an event witnessed by the speaker or based on hearsay. In constructions denoting uncontrolled bodily and mental processes (e.g., sweating, sneezing, bleeding, feeling sick), the experiencer is often marked by an object/dative pronoun and is the direct object. A noun denoting the bodily condition is, arguably, the subject or else there is no referential subject. There are usually clauses with nominal predicates denoting class membership and identifying relationships.

All TNG languages make extensive use of at least one of two types of complex (multi-headed) predicates to augment their stock of verbs. First, in verbal adjunct constructions, an inflected verb, usually carrying a rather general meaning, such as 'make', 'hit' or 'go', occurs in partnership with a noninflecting base (the verbal adjunct), which carries a more specific meaning. Verbal adjuncts partner just a small set of verbs. For example, Kalam has a single verb of sound making and speaking, *ag-*, but has some 30 verbal adjuncts that denote particular kinds of sounds and occur only with *ag-*. Second, in serial verb constructions, two or more bare verb roots occur in sequence to express a tightly integrated sequence of subevents; for example, Kalam: *d ap* (get come) 'bring', *d am* (get go) 'take', *am d ap* (go get come) 'fetch', *d nŋ* (touch perceive) 'feel', *ñb nŋ* (eat perceive) 'taste'. Many languages have a looser type of serial verb construction – narrative serialization – which allows a streamlined, formulaic representation of episodes in which the same actor performs a familiar sequence of actions; for example, Kalam: *am alŋaw-kab tk d ap ad ñb-* (go pandanus-nut gather get come cook eat) 'gather and eat pandanus nuts'.

Generally, little use is made of conjunctions to show sequential, conditional, and causal relations. Speakers commonly use long chains of clauses headed by medial verbs to report a sequence of past events that make up a single complex episode. In narratives, paragraph-like boundaries are frequently marked by head-tail linkage, in which the last clause of the previous sentence is repeated, to begin a new sentence.

Transformational Grammar: Evolution

S J Harlow

This article is reproduced from the previous edition, volume 9, pp. 4650–4664, © 1994, Elsevier Ltd.

Transformational grammar was developed in the mid 1950s by Noam Chomsky. Over the next two decades it became the dominant paradigm in syntactic theory and description and its descendant, government binding theory is still one of the most influential current theories. Transformational grammar forms a wide-ranging theory, whose central tenets are the use of hypothetico-deductive methodology to construct formal models of certain aspects of human linguistic capabilities. Such models are called 'grammars' in the theory and are taken to be an encoding, in some form, of the native speaker's linguistic knowledge (or 'competence'). Much of the work of transformational grammar has consisted of constructing models of (fragments of) individual languages, but equally important has been the task of exploring and defining the properties which are required by such grammars to provide accurate and revealing accounts of the linguistic data under consideration. Such general properties are taken to form the content of 'linguistic theory' (also termed 'universal grammar') and therefore do not need to be stated in individual linguistic descriptions. While a grammar for an individual language is a representation of the linguistic knowledge of the native speaker of that language, linguistic theory represents the properties (possibly very abstract in nature) which constrain all languages and thus defines the notion 'possible human language.' The content of universal grammar is taken to be a characterization of the human language acquisition device – those antecedent conditions that make language acquisition possible and which constrain the learning space available to the child acquiring a native language. Transformational grammar has undergone significant evolution since its initial development and one of the slightly ironic consequences of the pursuit of the goals listed above is that transformations themselves have come increasingly to play a less and less significant role in the theory. This article traces that development.

Early Transformational Grammar

Transformations, from which the theory derives its name, were developed during the 1950s by Zellig Harris and Noam Chomsky. The central idea underlying the concept of transformation was that of capturing systematic relationships between different syntactic representations. However, because of fundamental differences in the metalinguistic goals of Harris and Chomsky, the role played by transformations in the work of the two and the consequences of their introduction also were radically different.

Harris on Transformations

For Harris, transformations offered a way of allowing structural linguistics to transcend the limits of the sentence and offer a method of approaching discourse-level structures. For Harris, transformations are a device that extends the descriptive linguistic techniques of segmentation and classification to texts larger than a single sentence. They allow the linguist to establish equivalences between sequences of words in a text which would otherwise resist analysis. For example, suppose that a text contains the sentences:

(1) He played the cello.

(2) The cello was played by Casals.

but no sentences of the form:

(3) Casals played the cello.

(4) The cello was played by him.

In other words, there are no environments which show that *Casals* and *he/him* are grammatically equivalent (i.e., belong to the same grammatical category).

If, however, the text contains active/passive sentence pairs:

(5) He plays the guitar.

(6) The guitar was played by him.

an equivalence can be established between the two sentence types, as follows:

(7) $N_x V N_y \leftrightarrow N_y$ *was Ved by* N_x

Assuming that *He*, *him*, *Casals*, and *the guitar* belong to the category *N*, and that *played* is a member of the category *V*, (7) captures the relationship between the two; and between all other pairs of sentences possessing the same structure. With the equivalence given in (7) above, 'we can show that all the environments of *Casals* are equivalent to all those of *he*; and this in turn can make other equivalences discoverable textually' (Harris 1952: 129).

Chomsky on Transformations

For Chomsky, on the other hand, transformations formed part of a program directed at characterizing

the nature and properties of the human language faculty. Chomsky states:

> The development of these ideas that I would like to report on briefly, however, follows a somewhat different course. It begins by questioning the adequacy of a certain view of the nature of linguistic theory that has dominated much recent work, and it attempts to reformulate the goals of linguistic theory in such a way that questions of a rather different nature are raised. And finally, it attempts to show that the concept of grammatical transformation, in something like Harris' sense, but with certain differences, is essential to answering these questions (Chomsky, 1964b: 212).

One major difference between Chomsky's and Harris's applications of transformations was the nature of the representations between which a transformational mapping held. For Harris, the kinds of relationships captured by transformations were essentially those which in terminology developed later were called 'surface structure' relationships (Chomsky 1965a). That is to say, the mappings defined by transformations were limited to those which could be expressed in terms of the categories and linear order of the actually occurring words/morphemes in a sentence. For Chomsky, no such restriction was applicable. This is apparent in one of Chomsky's earliest and most well-known transformational analyses: that of the English auxiliary system. The abstractness permitted by Chomsky's conception of transformations allowed him to propose an elegant and simple analysis of the auxiliary system which, in the words of Newmeyer (1980: 24), "[...] probably did more to win supporters for Chomsky than all of his metatheoretical statements about discovery and evaluation procedures." In *Syntactic structures*, the book in which transformational grammar first became accessible to the linguistic community, Chomsky states:

> The study of these 'auxiliary verbs' turns out to be quite crucial in the development of English grammar. We shall see that their behaviour is very regular and quite simply describable when observed from a point of view that is quite different to that developed above. Though it appears to be quite complex if we attempt to incorporate these phrases directly into a [S, F] grammar [i.e., a phrase structure grammar] (Chomsky 1957: 38).

and proposes the following phrase structure rules:

(i) $Verb \rightarrow Aux \rightarrow V$ [28]
(ii) $V \rightarrow hit, take, walk, read, etc.$
(iii) $Aux \rightarrow C\ (M)\ (have + en)\ (be + ing)\ (be + en)$
(iv) $M \rightarrow will, can, may, shall, must$

$$\text{(i)}\ C \rightarrow \begin{Bmatrix} S \text{ in the context } NP_{sing\bar{a}} \\ \emptyset \text{ in the context } NP_{pl\bar{a}} \\ past[29] \end{Bmatrix}$$

Rule [28iii] states that an *Aux* phrase must contain as its initial element the tense/agreement morpheme *C*, and that this initial element can be followed by zero or more of *M*, *have* + *en*, *be* + *ing*, *be* + *en* in that order. *M* can then take any of the forms in [28iv]. Chomsky (1975: 232–33) observes, however, that:

> the sequence of morphemes which results from an application of [28] is not in the correct order. Thus to complete the statement we give the following rule [which later became known as 'affix hopping']:
>
> (ii) Let *Af* stand for any of the affixes *past*, *S*, *Φ*, *en*, *ing*. [29]
> Let *v* stand for any *M* or *V*, or *have* or *be* (i.e., for any nonaffix in the phrase *Verb*).
> Then:
> $Af + v \rightarrow v + Af\ \#$
> where # is interpreted as word boundary.
>
> (iii) Replace + by # except in the context $v \rightarrow Af$.
> Insert # initially and finally.

When the items *S*, *have* + *en* and *be* + *ing* in rule [28iii] are selected to give the string:

(8) $the + man + S + have + en + be + ing + read + the + book$

and rule [29ii] is applied three times (first to *C* + *have*, then to *en* + *be*, and finally to *ing* + *read*), followed by the application of rule [29iii], the following is derived:

(9) $the\ \#\ man\ \#\ have + S\ \#\ be + en\ \#\ read + ing\ \#\ the\ \#\ book$

Chomsky's analysis thus depends upon an abstract structure in which the affixes of the auxiliary system do not appear in their 'surface' order. The question of what kind of syntactic representations could legitimately constitute the input and output of a transformation came to be one of the most significant issues in the development of transformational theory.

In Chomsky's interpretation of the notion, a transformation is a mapping which converts a sentence (= a string of words) with an associated constituent structure analysis (= a 'phrase marker'), defined by a set of phrase-structure rules, into a new sentence with a 'derived constituent structure.' A transformation consists of a 'structural analysis' (often also called a 'structural description,' and abbreviated to *SD*), which specifies the sequence of categories into which a phrase marker must be analyzable for the transformation to apply to it, and a 'structural change,' which specifies the changes effected on the input phrase marker by the transformation. For example, the passive transformation is given by Chomsky (1957: 112) in the following form:

(10) Structural analysis:
$NP - Aux - V - NP$
Structural change:
$X_1 - X_2 - X_3 - X_4 \rightarrow X_4 - X_2 + be + en - X_3 - by + X_1$

(An alternative notation, which merges the structural analysis and structural change into a single statement of the form:

$NP_1 - Aux - V - NP_2$
$\rightarrow NP_2 - Aux + be + en - V - by + NP_1$

was also commonly used in later transformational work.)

The structural analysis specifies that for the transformation to apply to a string, the phrase marker associated with that string must be analyzable into a sequence of $NP - Aux - V - NP$. In the structural change, the variables $X_1 - X_4$ identify the four categories listed in the structural analysis and the string to the right of the arrow defines the mapping effected by the transformation: the relative positions of the two NPs are interchanged, the morpheme *by* is adjoined to the left of X_1 in its new position and the morphemes *be* and *en* are adjoined to the left of X_2 (= *Aux*). Each transformation is thus the composition of a number of more elementary operations, which include deletion, substitution of one element for another, adjunction, and permutation. For example, Chomsky (1965b: 120) specifies the operation of the passive transformation in terms of the following 'elementary transformation,' which details the operations performed by the rule:

(11) $tp(Y_1; Y_1, \ldots, Y_4) = Y_4$
[substitute Y_4 for Y_1]
$tp(Y_1, Y_2; Y_2, Y_3, Y_4) = Y_2$^be^en
[adjoin *be* and *en* t the right of Y_2]
$tp(Y_1, Y_2, Y_3; Y_3, Y_4) = Y_3$
[leave Y_3 unchanged (identity)]
$tp(Y_1, Y_2, Y_3, Y_4; Y_4) = be\hat{}Y_1$
[adjoin *be* to left of Y_1]
$tp(Y_1, \ldots, Y_n; Y_n, \ldots, Y_r) = Y_n$ for all $n \leq r \neq 4$
[identity]

This notation identifies each term in the structural description of the transformation by successively splitting the structural description into two substrings (indicated in 11 by the semicolon), one of which terminates with that item and the other of which begins with it. For each such item, the elementary transformation specifies what operation is performed on it.

As stated above, Chomsky's motivation for the introduction of transformations was radically different to that of Harris. Chomsky had established a hierarchy of language types, which could be used to model the properties of human languages. Each of the languages on the Chomsky hierarchy is defined in terms of the possible sequences of symbols it admits. Chomsky presented a proof that English possesses properties which mean that it cannot be analyzed in terms of the most restricted type of language on the hierarchy: 'finite state languages.' He also argued that any attempt to describe the syntactic properties of English in terms of the kind of devices available for characterizing the next weakest language type on the hierarchy ('phrase structure languages') leads to the loss of generalizations and greater complexity. The simple and elegant analysis of the English auxiliary system or of the passive outlined above, for instance, which require the capacity to rearrange the order of elements in a string cannot be accomplished within the limits of these more restricted grammatical systems. Chomsky concludes (1957: 44) 'By further study of the limitations of phrase structure grammars with respect to English we can show quite conclusively that these grammars will be so hoplessly complex that they will be without interest unless we incorporate such rules [i.e., transformations].' (It is, however, important to note that Chomsky did not *prove* that English could not be analyzed by phrase structure grammars at all. Rather, he argued that any such analysis would be unacceptably complex and unrevealing. Indeed, later developments in phrase structure grammars in the 1980s demonstrated that even this assertion is too strong.)

A grammar for Chomsky is a device which defines the language under investigation via a system of rules. In the earliest stages of transformational grammar (e.g., *Syntactic structures*), the grammar consisted of three sets of rules:

(12) Phrase structure rules
Transformations
Morphophonemic rules

As seen above, the phrase structure rules defined the constituent structures which form the input to the transformational component. The morphophonemic rules are responsible for ensuring, for example, that *take* + *en* is realized as *took*.

Subtypes of Transformations

Transformations in the early period fell into two categories, 'singulary' transformations, whose domain consisted of a single sentence, and 'generalized' (or 'double-based') transformations, with a structural description containing reference to more than one sentence. All the examples mentioned so far have been of singulary transformations. An example of a generalized transformation is the rule for coordination (Chomsky 1957: 113):

(13) Structural analysis: of S_1: $Z - X - W$
of S_2: $Z - X - W$
where X is a minimal element (e.g., *NP*, *VP*, etc.)
and Z, W are segments of terminal strings.
Structural change:
$(X_1 - X_2 - X_3; X_4 - X_5 - X_6) \rightarrow (X_1 - X_2 + and + X_5 - X_6)$

For example:

(Yesterday – John – left home; Yesterday – Sam – left home)
→ (Yesterday – John + and + Sam – left home),
where *John* and *Sam* are both instances of NP.

A further major class of generalized transformations were those that embedded one sentence in another. Chomsky (1964b) lists 19 such transformations, of which the following are representative examples:

(14) Nominalization
Structural analysis: S_1: T, $it + \varphi$, VP
S_2: NP, C, VP_1
Structural change:
$X_4 + S$ or φ replaces X_1; $ing + X_6$ replaces X_2

For example:

$$\begin{Bmatrix} \text{T} & -\text{it} + \text{C} & -\text{be} + \text{a} + \text{great} + \text{surprise} \\ X1 & X2 & X3 \\ \text{John} & -\text{C} & -\text{prove} + \text{the} + \text{theorem} \\ X4 & X5 & X6 \end{Bmatrix}$$

→ John + S – ing + prove + the + theorem – C – be + a + great + surprise

giving 'John's proving the theorem was/is a great surprise.'

(15) Complement
Structural analysis: S_1: X, V_T, *Comp*, *NP*
S_2: *NP*, *Aux*, *be*, *Pred*
Condition: X_2 is a member of the class of verbs containing *consider*, *believe*, ...
Structural change: X_5 replaces X_4; X_8 replaces X_3

For example:

$$\begin{Bmatrix} \text{They} + \text{C} & -\text{consider} & -\text{Comp} & -\text{the} + \text{assistant} \\ X1 & X2 & X3 & X4 \\ \text{the} + \text{assistant} & -\text{C} & -\text{be} & -\text{qualified} \\ X5 & X6 & X7 & X8 \end{Bmatrix}$$

→ They + C – consider – qualified – the + assistant

Following the application of an obligatory transformation which permutes the last two factors in the derived phrase marker, this gives *They consider the assistant qualified*.

This class of generalized transformation exemplified by (15) formed the locus of recursion in early transformational grammar, and was thus the mechanism by which grammars make available an infinite set of sentences from finite resources.

Rule Ordering

Transformations, in principle, could be ordered arbitrarily relative to one another (i.e., they were extrinsically, rather than intrinsically ordered). For example, the derivation of an interrogative sentence such as *Did John eat an apple* involved the application of the (optional) question–formation transformation:

(16) Structural analysis : $\begin{Bmatrix} NP - C - V \ldots \\ NP - C + M - \ldots \\ NP - C + have - \ldots \\ NP - C + be - \ldots \end{Bmatrix}$

Structural change: $X_1 - X_2 - X_3 \rightarrow X_2 - X_1 - X_3$

In other words, the tense formative C moves to the front of the sentence. The resulting derived P-marker requires the obligatory application of the word-boundary transformation [29iii] and the *do*-insertion transformation:

(17) *do*-insertion
Structural analysis: $\# - Af$
Structural change: $X_1 - X_2 \rightarrow X_1 - do + X_2$

(Adjoin the word *do* to the left of any affix immediately preceded by a word boundary.)

The successive stages of the derivation would look like this:

Phrase structure:	John – C – eat – the apple
Question-formation:	C – John – eat – the apple
Word-boundary:	#C#John#eat# the apple
Do-insertion:	#do + C#John#eat# the apple

($do + C$ is then converted to *did* by a morphophonological rule).

In order to correctly derive the sentence *Who ate the apple*, it was necessary to stipulate that T_w, the rule which moves an interrogative element such as *who* to sentence initial position, must apply *after* the question-formation transformation:

Phrase structure rules:	John – C – eat – the apple
Question–formation:	C – John – eat – the apple
T_w:	Who – C – eat – the apple
Word-boundary:	#Who#C eat# the apple

Do-insertion cannot apply to this structure, so affix hopping [29ii] applies obligatorily instead:

Affix Hopping: #Who# eat + C# the apple

Applying the two transformations in the reverse order would have the following effect:

Phrase structure rules:	John – C – eat – the apple
T_w:	Who – C – eat – the apple
Question-formation:	C – who – eat – the apple
Word-boundary:	#C # who# eat# the apple
Do-insertion:	#do + C# who# eat# the apple

This would give the ungrammatical **Did/does who eat the apple*. The only way in this analysis to avoid the generation of this ungrammatical string is to stipulate the ordering which gives the correct results.

In addition, a stipulation was required as to whether the application of a given transformation was either obligatory or optional. In the examples given above, the passive transformation is an instance of an optional rule, 'affix hopping,' [29ii] an instance of an obligatory rule – it must apply to any structure which meets the terms of its structural analysis. A sentence that is generated solely by the application of obligatory rules was termed a 'kernel' sentence. These corresponded to the class of simple, active, declarative sentences. Associated with the transformational derivation of each sentence was a representation called a 'T-marker,' which recorded which transformations had applied and in which order.

Transformations and Mental Processes

Although transformational grammar is intended as a model of the linguistic knowledge of the native speaker, it was not Chomsky's claim that the components of the theory were a model of the way the construction or comprehension of linguistic utterances is computed in the brain. Nonetheless, a number of experiments carried out in the 1950s and 1960s seemed to show that the transformational grammars developed for English during the early period did indeed make accurate predictions if taken as models of mental processing. In brief, these experiments seemed to show that there was a correlation between the number of transformations involved in the derivation of a sentence and the processing complexity associated with the sentence, measured in terms of some behavioral index such as response time – the greater the number of transformations involved, the greater the processing difficulty. For example, passive sentences take longer to process than their active counterparts and negative sentences take longer to process than their affirmative counterparts.

However, subsequent studies and a more mature assessment of the results of these experiments have shown that those experiments which seemed to show a positive correlation between transformational complexity and processing load did so because of a failure to control for other variables. It is well attested that processing load increases with sentence length. In the case of passive sentences, for example, *Albert was eaten by a lion* is two words longer than *A lion ate Albert*. Once such factors as this were controlled for, it became apparent that the derivational complexity hypothesis could not be maintained. It is universally agreed that the relationship between the form of a transformational grammar and the manner in which it is implemented in the brain is much more abstract and indirect than these early experiments suggested. It is therefore important to note that when linguists talk of a grammar 'generating' a set of sentences, there is no implication in the use of the term that the grammar is a model of human sentence production (see Carroll and Bever 1976).

The 'Standard Theory'

As Chomsky comments (1975: 23), "The theory of transformations developed in *The Logical Structure of Linguistic Theory* was far too unrestricted. It seems that there are much narrower conditions that determine the applicability of transformations and the kinds of mapping they can perform." The subsequent development of transformational grammar can be seen as a progressive transfer of many of the functions originally assigned to transformations to other components of the grammar.

There are five major areas in which this pattern of development can be seen:

1. Rule interaction;
2. Recursion;
3. Derived constituent structure;
4. The relationship of syntax to semantic interpretation;
5. The degree of abstractness permitted for underlying representations.

Rule interaction had presented a problem in the early theory of transformations because it was not clear what kind of ordering relationships could exist between singulary and generalized transformations. It was not clear whether, for example, singulary transformations could apply to an incomplete sentence structure *before* a generalized transformation embedded material in it. Various suggestions were made concerning the 'traffic rule' problem, but the most significant contribution was that of Fillmore (1963) who observed that it did not appear that there were any cases in which a singulary transformation had to apply to a structure before a generalized transformation embedded material in it. Second, it did not appear that it was necessary in practice to stipulate any ordering between generalized transformations, and third, there were attested cases where a singulary

transformation could apply to a sentence before it was embedded in a larger structure (passive, for example, in sentences such as *The director believed the keeper to have been eaten by one of the lions*). Fillmore's conclusion from these facts was that singulary transformations should apply first to (what would be) the most deeply embedded sentence. This sentence would then be embedded in the matrix sentence by a generalized transformation. This sentence would then become the domain of the singulary transformations again, and the process would be repeated as often as necessary.

Since transformations are mappings from phrase markers to phrase markers, it is essential that there be some well-defined way of specifying the constituent structure that results from the application of a transformation. The passive, for example, requires that the word *by* be adjoined to the left of the NP which has been moved into final position. It is clear that the resulting constituent should be a prepositional phrase, and that *by* itself should be a preposition. This information is not derivable, however, from the version of the transformation given above. Some linguists resolved this issue by specifying the details of the derived constituent structure in the structural change of the transformation itself:

(18) $NP_1 - Aux - V - NP_2 \rightarrow NP_2 - Aux + be + en - V - [_{PP}[_P\ by] + NP_1]$

This increasingly came to be considered an undesirable enrichment of the theory and alternatives were sought.

The problem of derived constituent structure also arose in the context of the application of generalized transformations. As can be seen from the complement example above (15), the transformation not only embeds material from one clause into another, but also deletes the subject of the embedded clause. The question then arises as to what the category of the embedded constituent is. The idea rapidly developed (Katz and Postal 1964) that clauses into which a sentence was to be embedded should contain a 'dummy' node, defined by the phrase structure component of the grammar, which would provide a host (and a category) for the embedded material.

These issues were addressed in the 'standard theory,' the name given to the revised version of transformational grammar developed by Chomsky in his book *Aspects of the theory of syntax* (1965a).

Rule Interaction: the Transformational Cycle

In *Aspects* the issues listed above received a radical answer, which reduced the role which transformations played in the theory. Most dramatically, the class of generalized transformations was eliminated entirely and their role as the locus of recursion was allocated to the phrase structure component. The issue of rule interaction was resolved by combining Fillmore's proposals with this innovation. Their joint effect is to require that transformations apply first to the most deeply embedded sentential structure, and, only when all possibilities have been exhausted, is the next 'higher' sentential level considered as a transformational domain. Graphically, the situation is illustrated in the schematic tree in Figure 1.

Figure 1

All transformations apply first to S_2, then to S_1, and only then to S_0. This principle of transformational rule application is known as the ('transformational') cycle.

By way of specific illustration, take the analyses of complementation by Rosenbaum (1967) whose thesis has proved a reference point for most subsequent work. Rosenbaum's work is concerned with the analysis of sentences such as the following:

(19) Sam prefers to stay here.

(20) I believe Bill to have been convinced by John.

(21) John is believed by me to have convinced Bill.

Each of these sentences would earlier have involved a generalized transformation. In the *Aspects* framework, the structures underlying them are provided by the following phrase structure rule:

(22) VP → V (NP) S

This rule preempts the role of generalized transformations by introducing the symbol S on its right-hand side. The structure associated with (19) by Rosenbaum's phrase structure rules (suppressing some details) is given in Figure 2.

On the lowest cyclic domain (the structure dominated by S_1) no rules apply. When the next highest cyclic domain (S_0) is reached, a 'complementizer placement' transformation is responsible for transforming this basic structure into:

Figure 2

Second Cycle: Sam prefers [for Sam [$_{VP}$ to stay here]]

This structure meets the structural description of what Rosenbam termed the 'identity erasure transformation' (now generally known as 'equi NP deletion,' or simply 'Equi'):

(23) Equi NP Deletion
Structural Description:

W	(NP)	X	+D	NP	Y	(NP)	Z
1	2	3	4	5	6	7	8

(Where + D identifies the complementizer *for – to*.)
Structural Change: 5 is erased (deleted) by 2

The effect of the application of this rule on *Sam prefers* [*for Sam* [$_{VP}$ *to stay here*]] is to delete the second occurrence of the NP *Sam*:

Second Cycle: Sam prefers [for [$_{VP}$ to stay here]]

which finally gives *Sam prefers* [$_{VP}$ *to stay here*]], through the application of a rule of 'complementizer deletion.'

For (20) and (21), Rosenbaum's analysis would provide the derivations in (20a) and (21a). (Note the use of the substructure [$_{MAN}$ by + P] in these derivations to provide a trigger for the passive transformation and a landing-site for the NP moved from subject position by the passive.)

(20a) *First Cycle*: I believe [$_{NP}$ it [$_{S}$ [$_{NP}$ John] [$_{VP}$ have + en convince Bill] [$_{MAN}$ by + P]]]]

Passive: I believe [$_{NP}$ it [$_{S}$ [$_{NP}$ Bill] [$_{VP}$ have + en *be + en* convince [$_{MAN}$ by + *John*]]]]

Affix Hopping: I believe [$_{NP}$ it [$_{S}$ [$_{NP}$ Bill] [$_{VP}$ have *be + en convince + en*] [$_{MAN}$ by + John]]]]

Second Cycle:

Complementizer Placement: I believe [$_{NP}$ it [$_{S}$ *for* [$_{NP}$ Bill] [$_{VP}$ *to* have be + en convince + en] [$_{MAN}$ by + John]]]]

Extraposition: I believe [$_{NP}$ it] [$_{S}$ for [$_{NP}$ Bill] [$_{VP}$ to have be + en convince + en] [$_{MAN}$ by + John]]]

Raising to object: I believe [$_{NP}$ *Bill*] [$_{S}$ for [$_{VP}$ to have be + en convince + en] [$_{MAN}$ by + John]]]

Complementizer Deletion: I believe [$_{NP}$ Bill] [$_{S}$ [$_{VP}$ to have be + en convince + en] [$_{MAN}$ by + John]]]

Post Cycle:

Morphophonemic Rules: I believe [$_{NP}$ Bill] [$_{S}$ [$_{VP}$ to have *been convinced*] [$_{MAN}$ by + John]]]

('Extraposition' is a transformation that takes a structure of the form [$_{NP}$ it S] and moves the S rightwards out of the NP.)

(21a) *First Cycle*: I believe [$_{NP}$ it [$_{S}$ [$_{NP}$ John] [$_{NP}$ have + en convince Bill]]] [$_{MAN}$ by + P]

Affix Hopping: I believe [$_{NP}$ it [$_{S}$ [$_{NP}$ John] [$_{VP}$ have *convince + en* Bill]]] [$_{MAN}$ by + P]

Second Cycle:

Complementizer Placement: I believe [$_{NP}$ it [$_{S}$ *for* [$_{NP}$ John] [$_{VP}$ *to* have convince + en Bill]]] [$_{MAN}$ by + P]

Passive: [$_{NP}$ it [$_{S}$ for [$_{NP}$ John] [$_{VP}$ to have convince + en Bill]]] *be + en* believe [$_{MAN}$ by + I]

Extraposition: it be + en believe [$_{MAN}$ by + I] [$_{S}$ for [$_{NP}$ John] [$_{VP}$ to have convince + en Bill]]]

Raising: *John* be + en believe [$_{MAN}$ by + I] [$_{S}$ for [$_{VP}$ to have convince + en Bill]]]

Affix Hopping: John be *believe + en* [$_{MAN}$ by + I] [$_{S}$ for [$_{VP}$ to have convince + en Bill]]]

Complementizer Deletion: John be believe + en [$_{MAN}$ by + I] [$_{S}$ [$_{VP}$ to have convince + en Bill]]]

Figure 3

Figure 4

Post Cycle:
Morphophonemic Rules: John is *believed* [$_{MAN}$ by + *me*] [$_{S}$ [$_{VP}$ to have *convinced* Bill]]]

In (20a) the passive transformation applies on the first cycle (inside the subordinate clause), whereas in (21a) it applies on the second cycle (in the main clause). In both derivations affix hopping applies twice, once on the first cycle and once on the second. Both these sentences also exemplify the rule of raising (called 'pronoun replacement' by Rosenbaum), which moves the subject of a nonfinite subordinate clause (here *John*) into the next higher clause on the second cycle. The existence of this rule was to become a major issue in the subsequent development of transformational grammar.

The Organization of the Grammar

With the adoption of the transformational cycle, many of the problems of rule interaction were satisfactorily resolved and, by the time of the publication of *Aspects of the theory of syntax*, the organization of the grammar took the following form (shown in Figure 3).

The 'lexicon' (formerly part of the phrase structure component) and Phrase Structure Rules were split into separate subcomponents of the 'base component' of the grammar and jointly determined a level of syntactic representation called 'deep structure.' This, on the one hand, provided the input to rules of semantic interpretation and, on the other, the input to the transformational component of the grammar, which mapped deep structure representations on to surface structure representations in the manner illustrated in (20a) and (21a) above.

Generative Semantics

The proposal that deep structure formed the level at which both lexical insertion and semantic interpretation took place came under strong challenge during the late 1960s. The branch of transformational grammar which became known as generative semantics argued that this conception of the organization of the grammar led to a loss of generalizations, a situation which could be remedied if underlying representations were allowed to be more abstract than Chomsky's deep structures. This aspect of generative semantics was driven by the Katz–Postal hypothesis (Katz and Postal 1964) concerning the relationship between syntax and semantics. This proposed that all the information necessary for semantic interpretation is represented in the underlying structure of a sentence. Corollaries of this proposal are that synonymous sentences have a single underlying structure and that ambiguous sentences have more than one underlying structure. It also implies that transformations do not change semantic interpretation.

For many sentence pairs, such as actives and passives, this proposal seems eminently reasonable. The assumption that *John saw Bill* and *Bill was seen by John* have the same deep structure and acquire their different surface forms through the application of transformations provides a basis for accounting for the fact that the two sentences have the same truth conditions. However, this logic, when applied to *Bill is dead* and *Bill is not alive* leads to the conclusion that they too must share a single underlying structure. In this case, however, such an identity in underlying structure must exist *before* lexical insertion, contradicting Chomsky's hypothesis about deep structure. This led McCawley (1968) to propose that the underlying structure of a sentence of the form *x killed y* should receive the analysis in Figure 4 (note that McCawley is assuming here that in its underlying structure English is verb-initial; see McCawley 1970 for details).

By the repeated cyclic application of an optional transformation of 'predicate raising,' the verbs in this structure could be adjoined to one another to give the structure in Figure 5.

Figure 5

Figure 7

Figure 6

Figure 8

McCawley proposed that 'if lexical insertion did not apply until after that transformation, then the "dictionary entry" for *kill* could be expressed as a transformation which replaces the subtree at the left [of the above tree] by *kill*' (McCawley 1968: 73). If lexical insertion is constrained to apply before all transformations, as in the *Aspects* approach, the semantic relationship between *x killed y* and *x caused y to become not alive* could not be expressed using transformations.

As an example of ambiguity prompting the postulation of different underlying structures, where purely syntactic evidence might not warrant them, take Lakoff's (1970) argument that the ambiguity of the sentence (24), with its two paraphrases (25) and (26):

(24) I don't beat my wife because I like her.

(25) It is because I like her that I don't beat my wife.

(26) It is not because I like her that I beat my wife.

could be accounted for by the assumption that the two readings correspond to different underlying structures. For (25), Lakoff proposed the structure in Figure 6.

For (26), he proposed the structure in Figure 7.

Transformations called 'it-deletion' and 'neg lowering' apply to these structures to give (24).

A further modification of standard transformational grammar made within generative semantics concerned the nature of the relationship which held between the various levels of a derivation. In standard transformational grammar, transformations are in effect relations between adjacent stages in a derivation. There was no possibility of a transformational 'looking forward' to a future stage in the derivation, for example. Generative semanticists, on the other hand, argued that such extensions were necessary. Lakoff (1971) observed that sentences like *Many men read few books* and *Few books are read by many men* seem to differ in their interpretations. The first is paraphrasable as *There are many men who read few books* and the second as *There are few books that are read by many men*. Lakoff proposed that these two interpretations are derived from different underlying structures. The first has the underlying structure in Figure 8, the second that in Figure 9.

The surface structures are derived by a transformation of 'quantifier lowering.' A problem remains, however, in ensuring that structure in Figure 8 must

Figure 9

undergo passive and the structure in Figure 9 must not. Lakoff's solution was to propose that passive and quantifier lowering could freely apply to both structures, but that a 'global derivational constraint' checked the relationship between the underlying and surface forms, requiring that the quantifier which was highest in underlying structure must be the leftmost one in surface structure. Global constraints allow the application of a transformation to have access to any level of representation in the derivation, not merely the information coded in its structural description and structural change.

In essence, what generative semantics did was to pursue the use of transformations to express linguistic regularities and subregularities to its logical conclusion. It assumed that transformations were the *only* way that such regularities should be captured, incorporating into syntactic description phenomena from semantics, pragmatics, and even social interaction. Ultimately, however, this central tenet of generative semantics was rejected by the majority of linguists working in the transformational framework. (A more comprehensive discussion of generative semantics and the factors both linguistic and nonlinguistic involved in its rise and fall can be found in Newmeyer 1980: ch. 4 and 5.)

The Extended Standard Theory

Subsequent developments in transformational grammar were motivated by a desire to constrain the expressive power of the transformational component. These took two forms. One was to seek to impose restrictions on transformations themselves, with the goal of limiting their expressive power; the other was to reallocate the responsibility for certain classes of phenomena to other components of the grammar, in particular the lexicon, the phrase structure component, and the semantic component. The name given to the version of the theory incorporating these revisions, which developed during the 1970s, was the 'extended standard theory.'

The work of Peters and Ritchie (1973) too undoubtedly encouraged a climate in which constraining the power of transformations was seen as desirable. They provided a proof that transformational grammars of the *Aspects* type had the weak generative capacity of the most powerful device on the Chomsky hierarchy, unrestricted rewriting systems (Turing machines). This meant that human languages, as characterizable by transformational grammars, had no particular properties other than that they could be generated by some set of well-defined rules. *Aspects*-style transformational grammar did not place any interesting constraints on the class of possible human languages. In terms of language acquisition, this implies that the formal properties of transformational grammars provided no interesting restrictions on the search space accessible to the learner. There was undoubted merit, in the light of these results, in any program which sought to constrain the power of existing transformational grammars.

The Lexicalist Hypothesis

'Nominalization,' referred to above, had been one of the earliest transformational rules proposed (see Lees 1966). Yet in 'Remarks on nominalization,' Chomsky (1970) developed the argument that at least some nominals which had previously been assumed to be transformationally derived were in fact simply basic lexical entries. His argument had two prongs. First, he demonstrated that the basis for the purported generalization was unsound and, second, that there were alternative ways of capturing the generalizations which remained.

In arguing against a transformational analysis of nominalization, Chomsky noted that what he termed 'derived nominals' (such as *refusal*, *easiness*, *revolution*, *belief*) do not occur in structures which are themselves derived by transformations. (The term 'derived nominal' does not imply any transformational derivation. Rather, the term is an allusion to the fact that such nominals form part of the derivational morphology of English.) So the sentences on the right of the arrows in (27) and (29) below are well-formed, but their corresponding derived nominals in (28) and (30) are not:

(27) To please John is easy ⇒ John is easy to please

(28) *John's easiness to please

(29) For John to win the prize is certain ⇒ John is certain to win the prize

(30) *John's certainty to win the prize

Furthermore, the semantic relationship which holds between a derived nominal and the item it is supposed to be derived from is frequently idiosyncratic. *John's deeds*, for example, are not the same as *things which John did*, nor is *John's ignorance* the same as *what John ignores*. In the common situation where there is no verb or adjective corresponding to a derived nominal (such as '*book*,' '*poem*'), the proponent of a transformational analysis is forced to postulate abstract underlying verbs such as *poetize* and to formulate mechanisms to ensure that these nonexistent items do not show up in surface structures (see, for example, Lakoff 1970).

To capture the regularities that do occur, such as *John refused to leave/John's refusal to leave*, *The enemy destroyed the city/The enemy's destruction of the city* and *The city was destroyed by the enemy/The city's destruction by the enemy*, Chomsky proposed first that in cases where there exists a verb/derived nominal pair, the lexical entry should be neutral with respect to grammatical category, but should specify what complements the pair require. In addition, he proposed an extension of the theory of phrase structure, known as 'X-bar theory,' to allow generalizations to be made across different linguistic categories.

For example, sentences and NPs have a similar internal structure (cf. Chomsky, 1970: 211). In (31) *the theorem* is the direct object of the noun *proof* and *John* is its subject. (This structure also requires the later insertion of the preposition *of*.)

(31)

In the corresponding sentence, *the theorem* and *John* hold exactly the same grammatical relations to the verb *prove*.

(32)

Chomsky also proposed that cyclic transformations such as passive could apply not only within sentences, but also within NPs, and proposed factoring the passive transformation into two subrules: 'NP-preposing' and 'agent-postposing.' The derivation of *The city's destruction by the enemy* would look like this (with various details omitted):

(33)

	The enemy('s) destruction the city by Δ
Agent-postposing	The destruction (of) the city by the enemy
NP-preposing	The city('s) destruction by the enemy

Note that the intermediate stage, resulting from agent-postposing, is also grammatical, provided that the NP's subject position is filled by a determiner. Exactly the same transformations apply in the case of the sentential passive *The city was destroyed by the enemy*, with the additional proviso that, for independent reasons, NP-preposing is obligatory.

Chomsky's argument, then, was that the generalizations captured by the nominalization transformation were spurious and, to the extent that genuine generalizations exist (such as the existence of active/passive pairs of nominalizations) there are alternative analyses available. The upshot of this was the proposal that transformations cannot change the syntactic category of an item. Thus, the rule of nominalization, as posited in early transformational grammar is not a possible transformation. This proposal was termed the 'lexicalist hypothesis,' because it assumes that any relationship of a crosscategorical kind is represented in the lexicon, and not by a transformational relationship.

Interpretive Semantics

The lexicalist hypothesis removes from the transformational component the power to alter syntactic categories and hence results in the reallocation of one class of linguistic phenomena to another component of the grammar. This is a tendency that is seen to be repeated with respect to other linguistic phenomena as the theory develops.

From the early days of transformational grammar, it had been assumed that the relationship that exists between an anaphoric pronoun and its antecedent, in sentences such as (34), where *Alice* and *she* can be interpreted as referring to the same individual, was to be captured by a transformation:

(34) Alice said that she should go.

The standard analysis of anaphoric pronouns (Lees and Klima 1969) assumed that they were derived from an underlying structure containing two identical occurrences of an NP. One of the NPs would be obligatorily converted into a pronoun by the pronominalization transformation:

(35) Pronominalization
$X - NP_1 - Y - NP_2Z \rightarrow X - NP - Y - NP_2[+Pro]Z$

where $NP_1 = NP_2$ [and various conditions on the topological relations between the two NPs were satisfied].

Jacendoff (1972) argued instead for a treatment of pronominal anaphora which relied on rules of semantic interpretation (an 'interpretive' approach to pronominalization). Jackendoff pointed out that the condition requiring identity between the two NPs (which must include not only syntactic identity but also identity of reference) is unexpected given that coreference is not generally a condition on the application of transformations; no movement rule, for example, is constrained to apply only to coreferential NPs.

Jackendoff's proposal assumed that anaphoric pronouns were base-generated in underlying structure and that rules of semantic interpretation established the necessary connection between them and their antecedents; no transformation of any kind was involved. This approach had a number of empirical consequences. It provided the basis for a solution to the problem that, in sentences containing quantified NPs such as *every runner*, the transformational treatment of prominalization predicts incorrectly that *Every runner expects that she will win* should have the interpretation associated with *Every runner expects that every runner will win*.

Furthermore, there are cases of anaphora which do not involve pronouns. Such sentences as *I wanted to help Harry, but the fool wouldn't let me* allow a coreferential interpretation of *Harry* and *the fool*. In addition, the conditions on the configurations in which anaphora is possible are shared by pronominal anaphors and by 'epithets' like *the fool*. For example, neither permit an anaphoric interpretation in sentences like the following *He/the fool said Harry would leave*. It is implausible to envisage a transformation giving rise to epithets, but no problems arise in principle in assuming that epithets are assigned interpretations by the same semantic rules that interpret pronouns. Note also that Jackendoff's proposal is consonant with the lexicalist hypothesis in not allowing a transformation to radically alter the morphological shape of lexical material.

The net conclusion of these and other arguments is that pronominalization is not a transformation and that the phenomenon of pronominal anaphora falls within the domain of the semantic component of the grammar.

Similar arguments apply to two other long-established transformational analyses; those of reflexivization and equi-NP deletion. Reflexivization was assumed to work in complementary distribution with pronominalization; roughly, where the latter applied to identical NPs which were separated by a clause boundary, the former applied to identical NPs in the same clause. Thus, *Mary was proud of Mary* would give *Mary was proud of herself*. Note, however, that when a quantified NP is involved, the result is the same as in the case of pronominalization; *Every runner is proud of herself* does not have the same interpretation as *Every runner is proud of every runner*. Equi-NP deletion, which derives *Mary wanted to win* from *Mary wanted Mary to win* exhibits the same phenomenon; *Every runner wanted to win* does not have the same interpretation as *Every runner wanted every runner to win*. As a consequence, proponents of the interpretive semantics position argued that neither reflexives nor the control phenomena handled by equi-NP deletion were the responsibility of the transformational component. Instead, reflexive pronouns should be basegenerated and interpreted by the semantic component. For 'equi' sentences it was proposed that the subject position of the nonfinite subordinate clause was filled by a basegenerated phonologically empty pronominal (PRO), also interpreted by the semantic component.

The result of these proposals was the removal from the transformational component of responsibility for a whole class of linguistic phenomena – those involving coreference – resulting in a more constrained theory of transformations and a superior account of the empirical data.

Constraints on Movement Rules

Structure Preservation The lexicalist hypothesis and interpretive semantics reduced the range of phenomena to be accounted for by the transformational component. For those transformations that remained, a major goal of the extended standard theory was to remove from the theory the capacity for individual transformational rules to contain detailed specifications of the conditions of their application, and to replace them with general conditions applying to all transformations, or to whole classes of transformations. This goal may be summarized as that of restricting the expressive power of transformations.

It was noted above that the precise manner in which the derived constituent structure resulting from the application of a transformation was determined was unclear and that various *ad hoc* measures were adopted, such as stipulating derived constituent structure in the structural change of the rule or introducing 'dummy' elements to act as the landing site of a moved constituent. This issue received a more highly-motivated solution in proposals by Emonds (1976). Emonds established three different classes of movement transformations:

(36) Root transformations
Those that crucially involved the root (roughly speaking the topmost) S node, and hence do not apply in subordinate clauses. Examples include Subject–Auxilliary Inversion (*Isn't it cold today*), Directional Adverb Preposing (*Down the street rolled the baby carriage*) and Topicalization (*Our daughters we are proud of*).

(37) Local transformations
Those that involve the reordering of two adjacent constituents, one of which is phrasal and the other nonphrasal. An example is Particle Movement (cf. *She picked up the book* and *She picked the book up*).

(38) Structure Preserving Transformations
Those that involve the replacement of a node by one of the same syntactic category. Examples include Passive, Raising, There-insertion (*A book is on the table* ⇒ *There is a book on the table*) and Dative Movement (*gave a ticket to John* ⇒ *gave John a ticket*).

The phenomena handled by root and local transformations have been subject to reanalysis more recently, but the essence of the structure preserving hypothesis has been accepted by all subsequent work.

Emonds argued, like Chomsky, that the passive transformation is in fact a composition of two separate rules: one that postposes the agent NP into the position of *by*-phrase object; and one that preposes the object NP into the vacant subject NP position. This requires that the derivation of *Germany was defeated by Russia* looks like this:

(39)

The structure-preserving hypothesis requires that the *by*-phrase be present in deep structure and that the NP within it be lexically empty (note that this implies that lexical insertion need not take place at deep structure). This analysis accounts for the fact that the passive *by*-phrase is like any other PP with respect to its internal structure and transformational behaviour.

Emonds points out that the fact that PPs under VP are generally optional in English, when combined with the structure-preserving analysis of passive, accounts automatically for the existence of agentless passives (*Germany was defeated*), in contrast to early analyses which had postulated a rule of by-phrase deletion.

Emonds's proposals constituted a step in the direction of removing from the structural description and structural change of a transformation the necessity, or even the possibility, of specifying where a constituent could be moved to; e.g., if the structure involved is not a root S and the transformation does not involve two adjacent constituents, the only possibility is for the moved constituent to move to a location in which the phrase structure rules permit a constituent of that type to be generated.

Blind Application of Transformations The 1970s saw major steps toward the goal of replacing conditions on specific transformations with general conditions which, instead of forming part of individual grammars, were a component of universal grammar. Chomsky (1973) noted that, if the structural description of the passive transformation in English were taken to be essentially:

(41) X, NP, V, NP, Y

with no reference to conditions requiring the two NPs to be members of the same clause (as had been standardly assumed), the transformation would apply to the deep structure analysis of a sentence like *I believe the dog to be hungry*, namely [$_s$ *I believe* [$_s$ [$_{NP}$ *the dog*] [$_{VP}$ *to be hungry*]] without the necessity for raising to move the NP *the dog* into the higher clause. Without any restriction on its operation, passive (and other transformations) would apply 'blindly' to any structural configuration meeting the structural description. Viewed in this way there is no problem in accounting for sentences such as *The dog is believed to be hungry by me*. Instead, there is a question as to why passive does not apply to *I believe the dog is hungry* to give **The dog is believed is hungry by me*. Chomsky's conclusion was that the failure of the passive to apply to the latter sentence is to be attributed to a general condition on transformational rules to the effect that no item may be extracted from a tensed (finite) clause. This constraint is phrased as follows:

(42) The Tensed-S Condition (TSC)
No rule can involve *X, Y* in the structure
... *X* ... [α ... *Y* ...] ... [where *a* is a tensed sentence]

Chomsky's discussion of reciprocals (*each other*) illustrates the application of the TSC. Following Dougherty (1970), he assumes that *each* in sentences such as (43):

(43) The men hated each other.

originates in deep structure as part of the subject NP as in (44):

(44) The men each hated the others.

and is moved out of it by a transformation ('each' movement) to give the structure in (43). The TSC explains why this movement is not possible in sentences like *The men each expected* [$_s$ *the others would win*] to give **The men expected* [$_s$ *each other would win*], and why movement of *each* is possible in the nonfinite counterpart *The men each expected* [$_s$ *the others to win*], giving *The men expected* [$_s$ *each other to win*].

However, given the grammaticality of *The men expected* [$_s$ *to shoot each other*], in which *each* appears in the object NP of the lower clause, the TSC does not account for the ungrammaticality of **The men expected* [$_s$ *the soldier to shoot each other*]. To account for this paradigm, Chomsky proposed the specified subject condition:

(45) Specified Subject Condition (SSC)
No rule can involve *X, Y* in the structure
... *X* ... [α ... *Z* ... – *WYV** ...]...

where Z is the subject of *WYV* in α, α is a cyclic node (NP or S) and α contains a subject distinct from *Z* and not controlled by *X*.

'Control' is the relationship which holds between PRO and its antecedent in 'Equi' constructions, or between a 'trace' (see below) and its antecedent. Any subject meeting the additional criterion in (45) is a 'specified subject.'

(46) We promised Bill [$_s$ PRO to kill each other].

and:

(47) *We persuaded Bill [$_s$ PRO to kill each other].

In (46) *each* originates in the deep structure as part of the NP containing *we*, which is the controller of PRO and moves into the subordinate sentence by 'each movement' (cf. 44 above); whereas in (47) the controller of PRO is the NP *Bill* which does not contain *each* at any level of representation. PRO in (47) is therefore a specified subject. Note that any phonologically realized NP (such as *the soldier* in (45)) is a specified subject, and also blocks the application of 'each' movement.

Under standard assumptions, there was an immediate counter-example to these conditions: the rule of *wh*-movement (so called because it moves phrases which contain the class of interrogatives and relatives that begin with the letters 'wh,' such as *who*, *which*, and *what* – as well as various others not fitting this description, such as *how*). *Wh*-movement is the rule responsible for deriving sentences such as:

(48) Who did John kill?

Since *kill* is a transitive verb, it is expected to have a direct object, yet no NP follows the verb in (48). The reason for this is that the requirement for an object NP is satisfied at deep structure, and the NP concerned, *who*, is moved to its surface structure position by a transformation.

In contrast to the transformations discussed so far, *wh*- movement has the property of being 'unbounded.' That is to say, that there seems to be no principled limit on the amount of material that can intervene between the deep structure position of the *wh*-item

and its surface structure position, as the following examples illustrate (the underscore marks the position from which *who* has moved):

(49) Who does Max think John killed_____?

(50) Who did Sam say Max thinks John killed_____?

Note that in these examples the clause which contains the extraction site of *who* is a finite one and, in addition, contains a specified subject (*John*). According to the TSC and SSC these sentences should not be possible.

Chomsky's solution to this problem was the radical proposal that, contrary to appearances, *wh*-movement is a cyclic rule. He adopted a proposal made by Bresnan (1970) that *wh*-movement involves moving the *wh*-phrase into the complementizer position of a clause – roughly speaking, the clause-initial position occupied by *that* or *whether*. This position, known as COMP, has the status of an 'escape hatch' for movement; movement to or from the COMP position does not violate the TSC or SSC.

The derivation of (50) would thus proceed as in (51):

(51) $[_{s'}$who$[_{s}$ did Sam say $[_{s'}$ COMP $[_{s}$ Max thinks $[_{s'}$ COMP $[_{s}$ John killed ___]]]]]]

To enforce the cyclic application of *wh*-movement (and prevent the movement of *who* in (51) from its deep to surface structure positions in one fell swoop), Chomsky proposed a further condition on movement rules: 'subjacency.' A node *X* is 'subjacent' to another node *Y* only if *Y* is higher in the tree than *X* and there is at most one cyclic node that dominates *X* and does not dominate *Y*. This is illustrated diagrammatically below, where α is a cyclic node (that is, NP or S):

The subjacency condition requires that no movement can take place from *X* to *Y* unless *X* is subjacent to *Y*. Checking (51) will confirm that the combination of COMP as the landing-site for *wh*-movement and subjacency precludes any other derivation than the one indicated.

Subjacency also provides an account for a class of phenomena known, since Ross (1967), as 'islands.' Despite the apparent unboundedness of *wh*-movement, it had been known for some time that there are constructions out of which *wh*-movement is prevented for some reason from moving *wh*-items. Chomsky (1964a) had observed that while the sentence *John kept the car in the garage* is ambiguous (meaning either that the car in the garage was kept by John, or that the car was kept in the garage by John), the sentence *Which car did John keep in the garage* is not, having only the latter reading. The nonexistent reading is the one in which the NP *the garage* is contained within the larger NP *the car in the garage*. Chomsky had proposed that in a situation like this, where a transformation might in principle apply to either of two NPs, in fact it must apply only to the larger one. This proposed constraint he termed the 'A-over-A principle.'

Ross (1967) gave a detailed investigation of a wide range of situations in which the application of unbounded movement rules was blocked. Ross pointed out that the A-over-A principle proved too strong in certain cases and identified the defining characteristics of the phenomenon as a set of structural configurations which he termed 'islands,' and proposed a corresponding set of 'island constraints' to restrict the application of unbounded movement rules:

(52) Complex NP Constraint (CNPC)
No item may be moved out of a complex NP by transformation, where a 'complex NP' is a structure of the following form.
Example:

Max met a man that sells books/what
*What did Max meet $[_{NP}$ $[_{NP}$ a man$]$ $[_{S}$ that sells ___]]

(53) Sentential Subject Constraint
No item may be moved out of a sentential subject by a transformation.
Example:
That John gave the book to Max/who surprised Sam
*who did $[_{NP}$ $[_{S}$ that John gave the book to _]] surprise Sam

(54) Coordinate Structure Constraint (CSC)
No conjunct in a coordinate structure may be moved, nor may any item in a conjunct be moved out of that conjunct.

Example:

Max spoke to Sam/who and Fred
*Who did Max speak to [$_{NP}$ – and Fred]

(55) Left Branch Condition
No NP on the left branch of another NP may be moved out of that NP.
Example:

You read Fred's/whose book
*Whose did you read [$_{NP}$ – book]

The subjacency principle serves to provide a unified account of all these island phenomena except the coordinate structure constraint. Note that in all other cases but coordinate structures, the movement involves a violation of subjacency. To illustrate with the last example, in **Whose* [$_s$ *did you read* [$_{NP}$— *book*]] two cyclic nodes, S and NP, intervene between *whose* and the extraction site.

Chomsky also proposed that subjacency would account for the prohibition on moving two (or more) *wh*-phrases out of the same clause (the *wh*-island constraint), as in **What* [$_s$ *do you wonder* [*who* [$_s$— *saw*—]]. On the assumption that, once the COMP node of the lower clause is occupied by *who*, it is no longer a possible landing-site for *what*, the only route to the topmost COMP will involve crossing two S nodes – a subjacency violation.

Trace Theory

The developments outlined in the preceding sections resulted in a situation where the substantive content of transformations had been severely reduced. Lexicalism had removed many linguistic phenomena from the domain of the transformational component, as had the reanalysis of phenomena involving coreference; structure preservation reduced the need to specify details in the structural descriptions of transformations, and subjacency limited the domain of application of transformations.

Chomsky (1973) had introduced the idea that movement of an NP left behind a 'trace' of itself. He developed this idea further (Chomsky 1976). He proposed that all movement transformations leave behind an phonetically empty copy (a 'trace') bound by the moved constituent and inheriting all its relevant properties. He points out the pattern of reciprocal interpretation (now effected by an interpretive rule, rather than the transformation of 'each' movement) supports the postulation of such an empty category in sentences involving raising to subject. There is a parallel between (56) and (57), where reciprocal interpretation in (57) allows *each other* and *the men* to be construed together, just as if they were in the same clause, as in (56):

(56) The men like each other.

(57) The men seem to John [*t* to like each other].

There is a similar parallel between (58) and (59), where reciprocal interpretation is blocked by the SSC. This insight is captured explicitly by the occurrence of a trace of NP preposing in (57) which participates in the interpretation of *each other* and one in (59) which forms a specified subject since it is bound by the singular moved NP *John*, blocking reciprocal interpretation with *men* just as the overt occurrence of *John* does in (58):

(58) The men want [John to like each other].

(59) John seems to the men [*t* to like each other].

Lasnik (1977) drew a parallel between the relationship which exists between traces and their binders and that which exists between PRO and its controller and between a reciprocal and its antecedent: always the binder must precede or asymmetrically 'command' the trace. (A commands B if the first S node that dominates A also dominates B.) This means that movement must always be leftward or to a higher position in a tree. Hence, raising is a possible movement rule, but its inverse, 'lowering,' would not be. Similarly, *wh*-movement must always be to a higher COMP node and never to a lower one.

With these developments, Chomsky proposed a constraint on transformations to the effect that the only categories that may be explicitly mentioned in a structural description are those that are changed (i.e., moved, deleted etc.) by the rule. He also suggests that a further step can be taken in the light of the structure preserving hypothesis, which entails that, for example, an NP can only be moved into another NP position. 'Thus the rules in question [e.g., passive] reduce to the following formulation: move NP' (Chomsky, 1976: 313).

All other details of the operations carried out by the rule are determind by general principles. The landing site being determined by a combination of the structure preserving hypothesis, subjacency, and Lasnik's condition.

This move was accompanied by a reinterpretation of the status of conditions like the TSC and the SSC, which ultmately spells the end of transformation grammar as such and its evolution into government-binding theory. At their inception, these conditions were construed as constraints on rules, blocking their application. Chomsky now proposed construing them

as conditions on surface structure wellformedness. That is to say, 'move NP' can apply freely, but the resulting representations must satisfy the TSC and the SSC. To take a specific example, *John seems* [*t to like Bill*] is the result of move NP and the trace is bound by an NP (*John*) as required by Lasnik's proposal. In **John seems* [*Bill to like* t], although NP movement has applied, the resulting configuration violates the SSC, on the assumption that the relationship between an NP and its trace is just like the one that holds between a reciprocal and its antecedent. The trace does not stand in the appropriate relationship to *John*, any more than *each other* does to *they* in **They expect* [*Bill to like each other*].

In 'On binding' Chomsky (1980) took this development a stage further and proposed that the SSC (renamed the 'opacity condition') and the TSC (renamed first the 'propositional island condition,' or PIC, and then the 'nominative island condition,' or NIC) should be reinterpreted as constraints on the occurrence of anaphors alone, rather than as relations between anaphors and their antecedents. The opacity condition took the form 'if α is an anaphor in the domain of the subject of β, β minimal, then α cannot be free in β, β = NP or S′. The nominative island condition took the form: A nominative anaphor cannot be free in S′. 'In the domain of' means 'c-commanded by,' where A c-commands B if the first branching node which dominates A also dominates B (a revision of Lasnik's 'precede or command'). 'Free' means not coindexed with a c-commanding antecedent. Nominative case is assigned only to the subjects of finite clauses.

To take up the analysis of *each other* to exemplify the revised framework, Chomsky suggests that all that need now be said about the distribution of *each other* is that it is a reciprocal. From this, within an appropriately articulated theory of grammar, will follow the requirement that it be bound by a plural antecedent within the same S′ or NP, if it is not itself a subject, so that (60) is grammatical with *each other* bound by *the students* within the minimal S′:

(60) John expected [$_{S'}$ the students to like each other].

(61), however, is ill-formed, because *each other* has no acceptable antecedent within S′:

(61) *The students expected [$_{S'}$ John to like each other].

(62) is ill-formed because the lower clause is finite. Its subject *each other* is therefore nominative and, according to the NIC, must be bound in S′. But, in this structure there is no possible c-commanding binder within S′, so the sentence is defined as ungrammatical:

(62) *The students expected [$_{S'}$ to each other would to like John].

Earlier, Chomsky (1977) had argued that what had been considered a range of different transformations should all be interpreted as expressions of *wh*-movement. These included not only *wh*-questions and relative clauses, but also topicalization (63a) (and its associated analysis in 63b), *Tough*-movement (64a) and (64b), comparatives and cleft sentences, although most of these do not occur with overt *wh*-phrases in them:

(63a) This book, I asked Bill to get his students to read.
(63b) [$_{S''}$[$_{TOP}$ This book] [$_{S'}$[$_{COMP}$ what] I asked Bill to get his students to read t]].

(64a) John is easy for us to please.
(64b) John is easy for us [$_{S'}$[who for] PRO to please t]].

(65a) John is taller than Mary is.
(65b) John is taller than [$_{S'}$[what] Mary is *t*]].

Chomsky's argument was founded on the claim that all these constructions exhibit the defining characteristics of *wh*-movement:

(66) a. it leaves a gap;
b. there is an apparent violation of subjacency, PIC and SSC;
c. it observes the complex NP constraint;
d. it observes *wh*-island constraints.

For example, the comparative in (67) and the *wh*-question (68) both demonstrate a violation of the complex NP constraint, while the comparative in (69) and the *wh*-question (70) both demonstrate parallel violations of the *wh*-island constraint:

(67) *Mary is taller than (what) Bill believes [$_{NP}$ the claim that she is –].

(68) *Who does Bill believe [$_{NP}$ the claim that she met –].

(69) *Mary is taller than (what) [I wonder [whether she used to be –]].

(70) *Who [does Bill wonder [whether she met –]].

The set of transformational movement rules was now reduced to two: 'move NP' and 'move *wh*' and in *On binding* Chomsky proposed that it could be reduced still further to 'move α,' where α is some category of the grammar. Move α will apply freely, but the resulting structures must satisfy the relevant constraints.

Transformational grammar, as it had been envisaged originally, was about to evolve into a theory in which transformations themselves played a relatively minor

role. The task of specifying the operations which transformations were entitled to perform was to be replaced by the task of specifying well-formedness conditions on the representations which resulted from the operation of transformations and other kinds of rules. The only constraint specific to transformations was, and remains, subjacency.

Transformational grammar constituted a major breakthrough in the investigation of the syntax of human languages and spawned an unprecedented amount of research, providing many new insights into language and its structure. It has been a topic of controversy since its inception, and a variety of alternatives now exist which challenge the very bases of transformational theory; but it is fair to say that many of them have developed in response to positions articulated within transformational grammar and it is doubtful that they would have come about without the stimulus and insights provided by transformational grammar. It is certainly true that our understanding of human language would be much impoverished had it not existed.

Transitivity: Stylistics Approaches

M E Ryder, Boise State University, Boise, ID, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction to Halliday's Notion of Transitivity

In stylistic analysis, 'transitivity' is used most often in the Hallidayan sense. The following is a simplified account of this aspect of Halliday's grammar (*see* **Systemic Theory**, Halliday and Matthiessen, 2004 and Thompson, 1996 for a more complete one). Transitivity refers to the linguistic system used to create experiential or ideational meaning, which is concerned with how entities and actions in a situation are coded in the language.

Processes, Participants, and Circumstantials

Although events and situations could be categorized in an infinite number of ways, the transitivity system divides them into six process types: material, behavioral, mental, verbal, relational, and existential. Processes are represented in a clause by the verbal group. Each process is connected with various participants, and any process can be accompanied by one or more circumstantials. Participants are inherent in a process; it is difficult or impossible to conceive of the situation or event coded by the process as being complete without at least one participant. Circumstantials, on the other hand, almost always express optional information. Although processes are categorized semantically, their semantic differences are reflected in grammatical patterns. Participants are coded as noun phrases, generally subjects, direct objects, or indirect objects, while circumstantials are usually expressed as prepositional phrases.

In material processes, "things happen, and people or other actors do things, or make them happen." (Halliday and Matthiessen, 2004: 170) Examples of verbs that encode material processes include *build*, *break*, *rub*, *deliver*, *shrivel*, *flatten*, and *meet*. The 'doers' in two-participant material processes are Agents and those in one-participant processes are Mediums. These roles are generally coded as subjects. Material processes often involve one or more other major participants, which differ in terms of the extent to which they are affected by the action. Goals, which are usually coded as direct objects, are the most affected. Recipients, usually coded as indirect objects, are generally less affected. Scopes are only marginally participants in the process; either they are not very affected, or they are not concrete entities at all, but are nominalizations of the process itself. Following are examples of these participant types:

(1) Peter repaired **the car.** (Goal)

(2) Catherine gave some books to **her students.** (Recipient)

(3) Walter crossed **the ocean.** (Scope, unaffected concrete entity)

(4) Mary sang **a song.** (Scope, nominalization of the process)

Mental processes are concerned with how we perceive the world or represent it to ourselves. Typical mental process verbs include *believe*, *know*, *see*, *want*, *like*, *frighten*, *doubt*, *remember*, or *regret*. These processes are prototypically states rather than actions. Mental processes involve two types of participants. The Senser is the conscious, usually human, entity that is in the state described. The Phenomenon is the entity, concrete or abstract, that is inducing the state. So, for example, in the sentence:

(5) Peter likes traveling.

Peter refers to the Senser and *traveling* to the Phenomenon. The range of entities that can be Phenomena is almost limitless. One grammatical result of this range is that Phenomena can be coded not only as noun phrases, but as subordinate clauses, as in:

(6) Peter likes to go to Europe with his wife.

Behavioral processes, represented by verbs like *worry*, *ponder*, *plan*, *sneeze*, *cough*, and *crouch*, fall into two subclasses, cognitive and physical. The cognitive ones are like mental processes, except that they are more eventlike; they usually refer to situations that are temporally bounded, as in:

(7) The cat dreamed about mice last night.

and/or to actions that are intentional, as in:

(8) Mary was thinking about writing a novel.

The physical behavioral processes are similar to material processes, except that they don't affect anyone other than the entity doing them, as in:

(9) Peter was sitting down.

and/or they are involuntary, as in:

(10) The baby laughed at her aunt's funny noises.

Behavioral processes have one main participant, the Behaver, the one performing the activity. Sometimes the process itself is "dressed up as if it was a participant" (Halliday and Matthiessen, 2004: 251), as in:

(11) He gave a great yawn.

in which case the participant role of the *yawn* is Behavior.

Relational processes are concerned with how we identify and classify entities. As such, like mental processes, they are prototypically states. Examples of verbs encoding relational processes include *be*, *remain*, *seem*, *exemplify*, and *have*. Relational processes are used for many related but distinguishable functions, including identifying, as in:

(12) That woman is a professor.

assigning an attribute, as in:

(13) That dog seems worried.

establishing possession, as in:

(14) Elizabeth has two cats.

or specifying any of a wide range of circumstantial types of information such as spatial or temporal location, content, or origin, as in:

(15) Boise is in Idaho.

(16) The meeting is at ten o'clock.

(17) The dress is (of) silk.

(18) The book is by Roberta Gellis.

For stylistic purposes, the several participants in relational processes can be combined into two, Identified and Identifier. The Identified is the entity about which information is provided and the Identifier is the information itself. Thus, in:

(19) The woman is a doctor.

the woman refers to the Identified and *a doctor* refers to the Identifier.

Verbal processes are those involving symbolically coded information being transferred between people. While the most prototypical verbal processes are those in which a person is actually saying something, any activity in which information is coded into language by a human being to be conveyed to another human being is considered verbal, as in sentences like:

(20) The report argues for more funds for education.

Examples of verbal process verbs are *speak*, *announce*, *promise*, and *ask*. The participants in verbal processes are the Sayer, the Receiver, the Verbiage, and the Target. The Sayer is the immediate conveyor of the message, which may be a person, but can also be the medium of the message itself, if a speaker is not present. So, in:

(21) The letter describes Peter as a wonderful person.

the letter is the Sayer. The Receiver is the audience; in:

(22) Susan told Jeff to sort the mail.

Susan is the Sayer and *Jeff* is the Receiver. The message itself is the Verbiage; *to sort the mail* is the Verbiage in (22). The Target is the entity that the verbiage refers to; in (21) above, *Peter* is the Target.

Existential processes involve something existing, as in:

(23) There are many short-sighted people.

The most common verb representing existential processes is *be*, but others include *exist*, *remain*, and *ensue*. Existential processes have only one participant, the entity that exists, which is the Existent. In (23) above, the *many short-sighted people* represent the Existent.

Lexicogrammatical Metaphor

In all of the above, it is assumed that there is an obvious one-to-one correspondence between the process, which exists outside of language, and the way it is linguistically coded. That is, processes will be realized by verbs and participants by nouns, and any given process will always be realized with a verb whose default meaning matches it. Neither of these is always the case. It is certainly possible for the default meanings of the words and the grammatical structure to be completely congruent with the actual event, as in:

(24) George destroyed the vase with a hammer.

However, it is equally possible to have encodings that are quite incongruent with the event, as would be the case if the situation just described were encoded as:

(25) There was a disintegration of the vase.

There is a continuum of encodings, with a range of possibilities between very congruent and very incongruent. For the event described above, the sentences:

(26) The hammer smashed into the vase.

(27) The vase disintegrated due to George's actions.

represent intermediate encodings. Any encodings that are not completely congruent are examples of lexicogrammatical metaphor. (Taverniers, 2003: 8)

Stylistic Applications of Halliday's Model of Transitivity

Point of View

There are a number of stylistic devices that contribute to creating point of view or focalization (Simpson, 1993; Toolan, 2001). One of the most straightforward involves the use of mental and cognitive behavioral processes. The Phenomenon in mental processes is usually accessible only to the Senser; for example, in:

(28) Sharon thought that she had wonderful parents.

the subordinate clause expresses information only known to Sharon. Likewise, many cognitive behavioral processes, such as dreaming or listening, are not readily observable from the outside, so only the Behaver will know they are engaged in that activity. Thus, for either type of process, the person involved will be the focalizer in that section of text, the person whose point of view is being represented. Transitivity choices also affect point of view in more subtle ways because they change the way different characters are viewed by themselves or by the reader, especially in terms of relative power or responsibility. This aspect of point of view will be discussed in more detail below.

Text Subworlds

There has been increasing interest in the role played by text subworlds (*see* **Text World Theory** and Werth, 1999) or mental spaces (*see* **Possible Worlds: Stylistic Applications** and Fauconnier, 1994) in a reader's comprehension of point of view and other aspects of a text (Stockwell, 2002: Ch. 7 & 10; Gavins, 2003; Semino, 2003). While subworlds can be set up by a variety of stylistic devices, among the most common are mental or verbal processes. These processes have in common that they can act as 'space-builders' (Fauconnier, 1994), creating subworlds containing the information introduced by the process. So, for example, in:

(29) Peter dreamed that a steamboat was being washed over the pier by the storm.

the verb *dreamed* creates a subworld containing the event involving the *steamboat*, *the pier*, and *the storm*. Likewise, in:

(30) Marion said, "I worked my way across the Atlantic on a tramp steamer."

the verb *said* creates a subworld containing the event involving *Marion*, *the Atlantic*, and the *steamer*. While the situations introduced into a subworld in these cases are described by a single subordinate clause, it is possible for a sentence containing a space-building verb to be followed by a paragraph, chapter, or even an entire work referring to a subworld; Coleridge's *Rime of the ancient mariner* (1798/1994) is a well-known example of this. So, (29) and (30) above could be followed by a virtually unlimited amount of text with additional information about the occurrences in the dream or verbal subworlds already established.

Coding Power and Responsibility

The aspect of transitivity that probably has the greatest potential utility in stylistic analyses has to do with what the choices of different processes and participants reveal about power relationships and assignment of responsibility for actions. In general, participants have significantly different degrees of power depending on how eventlike the process is in which they are involved. In a prototypical event, an Agent acting on their own intentionally causes a permanent change of state in a Goal, as in:

(31) The sculptor carved the marble.

In this case, the Agent will be represented as extremely powerful, especially in relation to the Goal, which will be represented as extremely low in power. As the process becomes less and less eventlike, there is less power involved, and it is more equally divided between the participants, as in:

(32) Katie touched the cat.

In addition, participants that are less directly connected to the event, such as Recipients and Circumstantials, neither have power themselves nor affect the power of other, more central entities, like *Elizabeth* and *the den* in:

(33) Katie gave Elizabeth a book in the den.

Among participants, the Existent and the Identified in existential and relational processes are the least powerful or active. The Senser and Behaver in mental and behavioral processes are more active, in that they are doing something, but they are still not particularly powerful, because generally their actions do not directly affect anyone or anything else. This situation changes somewhat if these participants are engaged in planning future actions. For example, if a heroine in a popular romance makes plans to exact revenge or to escape, she will appear more active and powerful than if she is simply fearing for her life or the hero's. This appearance is especially true if she carries out at least some of those plans later. The actions in verbal processes may also confer some power on the Sayer if the Verbiage causes a permanent change in someone else, as in an order for an execution, but often verbal activities have no permanent effect on others, making Sayers, like Sensers and Behavers, relatively low in power.

Material processes are the most eventlike as a class, but there is still a lot of variety within the category, resulting in differing degrees of power assigned to the participants. So, for example, if a character in a novel participates mostly as the Medium in a material process, they will be active but not particularly powerful, since no other entity is involved. And even in processes with two participants, the degree of the Agent's perceived power will be greater if the process involves a Goal than if it has the less-affected Scope, and if

there is a Goal, the Agent's power will be greater if the Goal undergoes a change of state rather than just a change of location. Thus, the subject's power increases from sentence (34) to (37), as the events described become more and more eventlike:

(34) The soldier went out on maneuvers. (Medium-only process)

(35) The soldier crossed the field. (Agent-Scope process)

(36) The soldier took the prisoner to the cell. (Agent-Goal process involving change in location of the Goal)

(37) The soldier shot the prisoner. (Agent-Goal process involving change in state of the Goal)

While it is possible to represent different participants as more or less powerful simply by choosing different types of processes for them to participate in, adding lexicogrammatical metaphor allows the author to create more complex stylistic effects by 'upgrading' or 'downgrading' processes. Researchers (Taverniers, 2003) have pointed out that grammatical metaphor, like lexical metaphor, requires that the reader understand both the literal and the metaphorical event codings to be able to comprehend the text. Thus, if a process at one point on the event continuum is upgraded by being metaphorically coded as one that is at a higher point, or downgraded by being coded as one at a lower point, having to process the literal meaning as well as the metaphorical one will make the situation described seem either more or less eventlike, with corresponding changes in the perceived power of the participants. This shift can be done merely by choosing a different verb within the same process type. For example, a material process involving change of state, as in:

(38) The assassin killed the president with a crossbow.

can be incongruently coded as a process involving change of location:

(39) The arrow traveled 15 feet before passing through the chest.

Compare this sentence with the syntactically parallel but congruent coding for a change of location:

(40) The car traveled 15 miles before passing through Rockville.

The metaphorical encoding in (39) not only makes the situation less eventlike by coding it as a change of location rather than a change of state, but it is now coded as a process with a Medium and Circumstantials only; the people involved, who would be the natural Agent and Goal, are either completely absent or referred to only indirectly. In general, any metaphorical encoding that recodes Goals as less affected participants or Circumstantials will decrease the perceived power of the natural Agent, and any encoding that codes less central entities as Goals will increase the perceived power of the entity coded as Agent.

A more drastic metaphorical change involves coding one type of process as another. For example, compare the congruent coding in:

(41) Elizabeth thought about her lovely granddaughter.

in which the situation is represented as a one-participant behavioral process, thus assigning no power to the participant, with that in:

(42) Thoughts of her lovely granddaughter engulfed Elizabeth.

in which the situation is coded as a two-participant material process with the *thoughts* in the position of Agent, and *Elizabeth* as a Goal, thus upgrading the power of the thoughts as well as process as a whole, and downgrading Elizabeth's power within the process. A classic example of use of lexicogrammatical metaphor to affect perceptions of power is William Golding's novel *The Inheritors* (1963), which portrays the worldview of the Neanderthals as one in which causation is almost never assigned to a person as a whole; instead, either a person's body parts, or inanimate objects, play the role of Agent or Medium (see Halliday, 1981 and Hoover, 1998 for transitivity analyses of this novel, and Short, 1976; Kennedy, 1982; and Simpson, 1993 for relevant transitivity analyses of other works.)

Power and responsibility are closely tied together, so any stylistic choice that changes perceived power will also change perceived responsibility. In fictional texts, the author can simply have characters participate in highly eventlike processes in order to represent them as having or lacking responsibility, increasing the effects by using lexicogrammatical metaphor if they choose. In reporting real events, authors are more likely to attempt to change the perception of responsibility by using metaphor, rather than changing the events themselves. The effects of using incongruent coding are especially noticeable when there is a great deal of responsibility involved, as is the case in highly eventlike situations. For example, the situation congruently coded in:

(43) The army bombed the city and killed many civilians.

involves two permanent change-of-state material processes represented as main verbs, and clearly assigns both the power and the responsibility for the events to *the army*. However, the coding can be downgraded significantly, as in the incongruent sentence:

(44) The city's bombardment and the resultant loss of life were necessary for national security.

in which the main process, expressed by *were*, is relational. This coding not only transforms material events involving catastrophic changes of state in the Goals into a static situation, but it allows the participants who are the natural Agents to be removed from the sentence altogether.

Basic Narrative Structure

Basic narrative structure has been discussed by a number of researchers (*see* **Narrative: Cognitive Approaches** and Toolan, 2001: Ch. 6 for a summary.) While there are significant differences in opinion about the extent to which there is a basic structure common to all narratives, certain components appear in many analyses. These include orientation, complicating action, resolution, and evaluation. Because they serve different functions, these components have noticeably different distributions of processes (Halliday and Matthiessen, 2004: 174). The orientation, also called the setting, introduces characters and locates the narrative in a particular time and place. As a result, existential and relational processes, often accompanied by a high number of Circumstantials, will predominate. The complicating action and the resolution contain the main events in the narrative, delineating the cause-effect chain that holds the story together. These sections will therefore generally be dominated by material clauses, although as Toolan (2001: 153) points out, verbal processes may be part of the cause-effect chain as well.

The evaluation component of a story is more complex and often harder to separate out than the other parts of a narrative. Evaluation includes

> all the means used to establish and sustain the point, the contextual significance and tellability, or reportability, of a story. It may take many forms and appear at almost any point in the telling . . . (Toolan, 2001: 151).

At least in external evaluation, which appears in clauses separate from those coding the complicating actions and resolution, there will generally be a predominance of relational and verbal processes, as the author either has the narrator evaluate the situation, as in:

(45) It was an amazing experience.

or places the evaluative clauses in the mouth of a character, as in:

(46) Elizabeth said, "I've never had something so amazing happen to me."

While these components are easiest to identify in simple oral narratives, many of the same patterns are also recognizable in longer, more complex texts. For example, sections where the narrative departs from the main cause-effect chain will often show a concomitant shift from predominantly material to nonmaterial processes. In descriptive sections, as in orientation sections, existential and relational processes will predominate. A section in which a character remembers the past, muses over the present, or considers the future, will probably contain a number of mental processes, building often quite complex textual subworlds.

Genre Analysis

Just as different components of a basic narrative show different process patterns, so do different genres to varying degrees (*see* **Genre and Genre Analysis**). First, there is a basic difference in patterns between narrative and expository/argumentative texts, in that, unlike narratives, expository texts will have a significantly greater proportion of relational to other processes. Moreover, scientific writing in particular and writing in an academic register in general show an extremely large number of instances of a particular type of lexicogrammatical metaphor that construes entire events as entities that act as participants in relational processes (Halliday, 1988). Thus, rather than saying:

(47) I put 40 mice in an enclosure suitable for 5 and after a week, they were constantly fighting with each other.

an author will use nominalization metaphors, as in:

(48) Overcrowding of the rodents was correlated with heightened aggression.

Within fiction, subgenres often show different patterns of processes. For example, romance fiction generally has a significantly higher percentage of verbal, behavioral, and mental processes than do action books such as westerns and spy or crime thrillers (Nash, 1990). Use of these types of processes, along with material processes involving movement, serves to make heroines appear active without being powerful (Nash, 1990; Ryder, 1999). This appearance is accomplished by coding the heroine as the subject in a main clause, generally a fairly powerful position, while making the process in which she participates active but not very eventlike. Use of lexicogrammatical metaphor to code normally one-participant processes as transitive verbs also allows

the heroine to look more powerful as well, by turning Circumstantials into Scopes or Behaviors:

> (49) Delia paced the room, occasionally giving an impatient sigh. She picked up the letter, unfolded it, read it for at least the tenth time, then folded it again and put it back on the mantel.

In the first sentence in (49), two inherently intransitive processes, pacing and sighing, have been upgraded by making them transitive and adding a Goal and a Behavior, and the second sentence contains a string of transitive processes, but none of them creates a change in state of the Goal.

Mysteries also generally contain a relatively high percentage of verbal, mental, and cognitive behavioral processes, but these processes serve a somewhat different purpose in this genre than they do in romance. The author must provide the reader with all the information necessary to resolve the mystery without making the information so obvious that there is no puzzle to solve. One of the easiest ways to accomplish this negotiation is to provide the reader with a variety of subworlds set up by verbal processes, containing conflicting versions of the facts provided to the detective by the various witnesses and suspects. In addition, the detective as well as other characters are represented as considering various solutions to the mystery, which are coded as subworlds created by mental processes. (See Simpson, 1993; Stockwell, 2000; and Ryder, 2003 for process analyses of various other fiction subgenres.)

Critical Discourse Analysis and Feminist Stylistics

Critical discourse analysis and feminist stylistics both examine how stylistic choices in a text construct unequal positions for different social groups, and how the representation of disempowered groups can be analyzed and altered to redress the inequality. Critical discourse analysis (CDA) has a number of strands, but most CDA researchers agree that discourse, both spoken and written, helps produce and sustain, but also transform, unequal power relationships (*see* **Critical Discourse Analysis**). This primary concern with power and its representation makes transitivity analysis a particularly attractive analytical tool. CDA has been applied to a wide variety of texts, concentrating on those in the public sphere (Trew, 1979). In all cases studied, an analysis of the types of processes, participants, and lexicogrammatical metaphors found in the text reveals that certain groups are coded as having more power or responsibility than others, even when casual readers, or the writers themselves, may not have realized that the text contained such consistent patterns.

> Researchers in feminist stylistics attempt not only to describe sexism in a text, but also to analyze the way that point of view, agency, metaphor, or transitivity are unexpectedly closely related to matters of gender (Mills, 1995: 1).

(*see* **Stylistics, Feminist**). Like CDA, feminist stylistics studies include analyses of a wide variety of texts, but there is a central concern with media and advertising representations of women (Clark, 1992), and the representation of female characters in romance novels (Christian-Smith, 1989; Ryder, 1999; Wareing, 1994). As in CDA studies, these analyses generally show that consciously or not, those supporting the present power structure choose patterns of processes and participants that consistently code women as generally passive and powerless on the one hand, but on the other hand, as responsible for many of the crimes in which they are victims. This picture is complicated by studies showing that in some texts written by women, the authors have found ways to 'have their cake and eat it, too,' that is, to appear to be obedient to the dominant group's rules while still defining themselves in opposition to them (Mills, 1997), or have shown women as powerless as a form of protest (Burton, 1982).

Cautionary Note

Several authors have argued that stylistic effects cannot simply be 'read off' transitivity patterns in a text, because the same patterns seem to have quite different results in different texts (Fish, 1981). However, as Simpson (1993: Ch. 4) has pointed out, combining information about the general effects of certain transitivity patterns with the specific context of an individual text does in fact produce insightful analyses. Simpson compares passages from *The Inheritors* (1963) and *Pincher Martin* (2002), both by William Golding and both exhibiting strikingly similar transitivity choices that represent characters as powerless. Simpson points out that, while the personalities of the characters in the two passages are quite different, the similarity in transitivity choices still makes sense, since both characters lack power even though in one case, it is because of lower innate intelligence, and in the other, it is because the character is drowning. Simpson concludes that "isolating an interpretive 'lowest common denominator' in this way . . . high-highlights the fact that both texts, despite markedly divergent story lines, are at one level of analysis, stylistically very similar" (Simpson, 1993: 113).

Translation and Genre: Drama

G Anderman, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

While drama translation for the page has much in common with translation in other literary genres, transferring a play from one language into another for performance on stage presents the translator with problems of a different order. Unlike the reader of a play, a theatre audience is not in a position to consult footnotes or encyclopedias containing information about unfamiliar cultural concepts and social situations. With the exception of explanatory comments provided in performance programs, audiences are left

to fend for themselves when confronted with unknown, often bewildering information. Also of importance is the notion of performability, the ease with which director and actors can make a play come to life, an outcome crucially dependent on the use of spoken rather than written language. Often an indicator of class, education and geographical origin, the language of the different characters in a play is uniquely defined by their idiolect, sociolect and dialect, which often do not travel easily in translation. In addition to other linguistic obstacles, there is also the potential problem of the kind or genre of the play to be translated. A play originally conceived as expressionist or symbolist, does not normally benefit from a naturalist approach to the dialogue in translation. Finally, there is the question of direction of translation; global awareness of Anglo-American language and culture greatly facilitates translation out of English, leaving the translator of plays originating in other languages wrestling with problems of a different nature, often resulting in the need for re-writes, versions and adaptations in English translation.

Foreignizing vs. Domesticating

When transferring a play from one language into another, two contrasting approaches may be recognized: the playwright may be left in peace as much as possible and the audience sent abroad or the audience may lean back in comfort while the playwright is brought closer (Lefevere, 1977: 74). In short, the translator may opt for a *foreignizing* or *domesticating* approach (Venuti, 1995). While the former entails retaining alien allusions and references, the latter strives to neutralize culture-specific elements and may even relocate the play to the country of the target language in order to facilitate audience understanding of a play. An example of this strategy is David Johnston's translation of *Luces de bohemia, Lights of Bohemia*, Ramón Valle-Inclán's play set in the Madrid of 1918/1919, proliferating in social, cultural and literary Spanish references. In order to make his version more easily accessible to an English audience, the setting of the play was moved from the post-Bolshevik disturbances of Madrid and relocated to Dublin just before the Easter Rising (Johnston, 2000). Relocation is also the strategy employed in the creation of the English version of *Natale in casa Cupiello*, *Christmas at the Cupiellos*, by Italian playwright Eduardo de Filippo as a solution to the problem of transferring the Neopolitan playwright's dialect in translation. Retitled *Ducking out,* this close study of family life was moved to Yorkshire, home ground of the adaptor, British playwright Mike Stott.

Familiarity with the Target Language and Culture

The risk of an English audience failing to understand references to cultural concepts and social situations is, however, less likely to be of concern in the translation of French plays. Close historical links and geographical proximity between France and the UK as well as French being the first foreign language taught at English schools have created a situation allowing playwright and translator Neill Bartlett to comment on his translation of Jean Genet's use of puns in his play *Splendid's* that "[a]ny reader who thinks my choice too bold should consult the French text in order to trace the originals of my puns" (Bartlett, 1995: xvi). Of equal help to the translator is the preponderance of French loanwords in English, making it possible for instance to retain the title of Jean Cocteau's 1937 play *Les parents terribles* for performance in London while a greater distance to the play's country of origin necessitated a change to *Indiscretions* when transferred to New York. Still, on other occasions, the translator may be less inclined to greet the presence of French loanwords in English with enthusiasm. While Anglo-Saxon words and expressions belong to the register of everyday usage, French terms in English are often associated with a more elevated style of discourse. Whereas a play such as *Messe solennelle pour une pleine lune d' été, Solemn mass for a full moon in summer,* by Quebec playwright Michael Tremblay contains words that belong naturally to a French vernacular idiom such as *apathie, violence, insensibilité*, English cognates such as "apathy, violence and insensibility" fit less comfortably into non-standard language while proving difficult to replace by Anglo-Saxon equivalents (Bowman, 2000). However, this problem in translation is compensated for by the retention of French place names and characters addressing each other as 'Madame' or 'Monsieur,' thus allowing French plays to remain foreign in the sure knowledge that for an English theatre audience, 'the other' is not alien to the point of causing consternation.

Confronted with the work of playwrights writing in other less well-known languages, audience response may be different. Retaining the Russian form of address, including the use of patronymics in respectful conversation, not only places a burden on the memory of English actors but also on the audience, drawing early critical complaints that Anton Chekhov's plays inevitably entailed a stage "inscrutably occupied by Mishka Vaselenovitch Klooglosevtloff, a retired professor . . . and a very puzzling assortment of Pishkins, Boraptakins, Sergius Vodkaroffs, Abrezkoffvitchs and Olthidors . . ." (Senelick, 1987: 292).

Spoken Language and Dialects

Full awareness that drama requires the spoken mode to be matched in translation is relatively recent. Before naturalism reached the stage in the form of the modern drama, the way ordinary people speak was of little interest as it was not considered appropriate language to be used on stage. When, in 1914, *Pygmalion* first opened at His Majesty's Theatre in London, critics did not take kindly to the use of expressions such as "not bloody likely." George Bernard Shaw had met the linguist Henry Sweet, with whom Professor Henry Higgins of *Pygmalion* and subsequently *My fair lady* shares many characteristics in the early 1880s and was well aware of the way in English dialect and sociolect interact to make language an indicator of class and education. In translation, however, both contrive to make full appreciation of the original far from easy. An example of the problems in the translation of plays written in dialect is provided by the work of Gerhart Hauptmann. Written in 1892, *Die Weber, The weavers*, based on a real-life uprising of a group of hand-loom weavers in the 1840s, established the German naturalist writer as a leading European playwright and, in 1912, earned him the Nobel Prize for Literature. Written in Silesian dialect, making an authentic match of the original in translation into standard English difficult to achieve, more recently the spirit of Hauptmann's play has been captured in a Scots dialect version by Bill Findlay where the numerous linguistic options in German have found their counterpart in the number of flexible linguistic choices available in Scots such as urban vs. rural, regional vs. standardized, historic vs. contemporary (Findlay, 1998). Also translated into non-standard English for performance in translation from Russian is the work of Anton Chekhov. In an attempt to avoid associations of the Home Counties to be evoked by a translation into Standard English, Irish playwright and adaptor Thomas Kilroy relocated *The seagull* to Ireland, which enabled him to use Hiberno-English for the translation, a variety of English different in grammar and syntax from the speech of mainland England.

Grammar and Syntax-Linked Problems

Other linguistic obstacles facing the translator of drama is the problem presented by "untranslatable" words and expressions, a situation made particularly difficult if the term or expression is used thematically throughout a play. If, for instance, an innovative phrase or expression draws on language-specific syntax and grammar, absence of equivalence may necessitate the use of paraphrasing. Characteristic of Ibsen's creative use of Norwegian is his style of compound formation whereby new, transparent nouns and adjectives are created by combining already familiar words into novel concepts. A well-known example is *lysrædd*, literally meaning 'lightfrightened,' used by Ibsen in *Ghosts* in order to describe a household where a carefully constructed web of lies keeps in the dark everything that does not stand up to closer scrutiny. Similarly the Swedish dramatist August Strindberg, whose fast-paced action is often achieved through the creation of compounds such as *sjalpåtagning,* literally 'shawl-putting-on,' which as "helping her on with her shawl" inevitably loses in immediacy, economy and humor in English translation (Sandbach, 1985: 30–33). The process of compound formation allowed by the grammars of Norwegian and Swedish is paralleled in German while less easily matched in English, not characteristically Germanic in a number of syntactic and grammatical respects.

In translation between German and English, there is yet another related problem presented by the use of prefixes and suffixes in the two languages. Bertolt Brecht's well-known dramatic principle of *Verfremdung* (making unfamiliar) or V- effect is not only an intriguing theatrical strategy but also a term, far from easy to translate into English. While the prefix ver- travels with ease between other Germanic languages as does the suffix -ung, in English Brecht's proposed process of making something seem less familiar is often rendered through the French loan "alienation" leaving open the possibility of an interpretation involving negative connotations.

Nor is drama translation between Romance languages and English altogether free from grammar and syntax-linked problems. While a language such as Italian allows pronominal subjects to be omitted, English does not, at times resulting in wordier constructions in translation. At the beginning of Luigi Pirandello's play *La vita che ti diedi*, *The life that I gave you*, Donn'Anna's only son lies dead; here key words such as *vita* 'life' and *morte* 'death' along with their derived forms are juxtaposed. Act II concludes with one word from Donn'Anna: *vive*. In English translation, this single key word becomes three; 'he is alive,' reducing the succinct impact of one single word at a crucially theatrical moment of the play (Anderman, 2005). Not infrequently, the problem in Pirandello translation starts as early as the title of the play (Bassnett-McGuire, 1983). For instance, while *Cosi è (se vi pare)* contains a light, jocular note, this could hardly be said about the English titles under

which the play is often known: *Right you are (if you think so)* or *It is so (if you think so)*.

Genre and Kind of Drama

In the case of Pirandello's countryman Dario Fo, 1997 Nobel Prize laureate, problems in translation are closely linked to genre. Writing in the tradition of *commedia dell'arte*, a hard-hitting while entertaining form of political satire, a Fo play such as *Accidental death of an anarchist* has often emerged in English as a farce but with its emphasis on the play's humorous aspects, part of its bite lost in translation. As the tradition in which Dario Fo writes may become blurred, so too is often the style in English translation of the plays by Federico García Lorca. It is not always remembered that a play such as *Yerma* is as much a poem as it is a play and that a translation that may be right for naturalistic intensity will not necessarily do justice to the original language of the work of the Spanish poet and dramatist.

Direction of Translation

Translation of English and American plays into other languages on the other hand poses considerably fewer problems than translation in the opposite direction. The position of English as a global language and, in addition, the virtual hegemony of the Anglo-American literary tradition, normally ensures relatively faithful renderings of the source text with less need for adjustment to facilitate comprehension in the translation of plays written in English. The impact of this lack of equivalence that manifests itself in translation has been given a theoretical explanation by the Israeli scholar Itamar Even-Zohar who views a given culture as a 'polysystem' or system of systems. In the dialogue between these systems, an imbalance prevails in the power relations that hold between them: at a given time in history, a particular system is likely to be stronger than another one (Even-Zohar, 1990). For many centuries, center position in the world of theatre was held by French playwrights which, for the first stage production of *Hamlet* at the Comédie Française, led the translator Jean-François Ducis to feel entitled to domesticate Shakespeare's play in order to meet the neo-classicist demands for unity of time, place and action. As a result, in translation into French, Hamlet never leaves Elsinor where the action takes place during an uninterrupted period of 24 hours with all subplots removed, including the death of Ophelia (Heylen, 1993: 26–44). And the period 1850–1870, the French influence on cultural life in Britain at its peak, saw English playwrights put a Parisian success on the London stage in various degrees of adaptation, spawning not only one but sometimes several English versions of the original (Hale, 2000).

In the early 21st century, French literary supremacy has given way to Anglo-American hegemony, with accompanying norms dictating the translation of drama. This situation notwithstanding, the European canon is increasingly finding its way onto English-speaking stages in translation, versions, and adaptations. With the growth of globalization, in time to come there might even be a chance for drama from beyond Europe to emerge fully, bringing with it a different set of linguistic problems, in turn requiring new solutions in translation.

Translation and Genre: Literary

M Gaddis Rose, Binghamton University, Binghamton, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

To put it plainly, 'genre' means a kind or type of rhetoric. Furthermore, the term can be applied to any stylistically consistent utterance, whether oral or written, literary or non-literary. Major literary genres are drama, poetry, fiction, and essay. Each major genre has many a subgenre like tragedy, sonnet, tale, or sermon. As a term, genre, derived from *genus* (any class of things that can be divided into subclasses), comes to translation studies via literary history and criticism and by extension to translation criticism and practice. It is the umbrella term, favored by literary tradition. Thus, translation criticism and practice, where humanistic literary studies are uppermost, tend to refer to genres. On the other hand, very similar strategies of discourse analysis, when emanating from linguistics, are termed text types. It should be born in mind that the differences between genre and text type, if any, are subtle and probably immaterial.

Veritably every philosopher who takes up language has at least an implicit theory of genre, and every major literary critic or historian usually has an explicit theory of genre. However, in the second half of the 20th century, the undisputed giants of genre criticism have been Mikhail Mikhailovich Bakhtin (1896–1975), Georg Lukacs (1885–1971), and Northrup Frye (1912–1991). By and large, students pursuing genre will find more open discussion in the period norms of Structuralism and Modernism, which were the prevailing fashions down through the years immediately following World War II, than in Poststructuralism and Postmodernism, which have dominated the past quarter century. Oversimplified, Structuralists and Modernists such as Claude Lévi-Strauss and T. S. Eliot tend to show the patterns underlying detail and hence support the classifications of literary genres. Poststructuralists and Postmodernists like Michel Foucault and Edward Said point out the distortions caused by zealously applied taxonomies. Translation theorists move with cultural history and keep their own perspectives attuned. Eugene Nida (1912–) and André Lefevere (1947–1997) have been conspicuous examples of theorists who integrate the contributions of successive critical strategies. Literary translation follows literary fashions and usually precedes translation theory, so the taxonomy comes after the example. In translation practice, the usefulness of genre as an initial identifying text marker is obvious. The rhetorical conventions inscribed in a genre both compose a tradition and present a guide. Thus, if translators identify the genre at the outset of a translation project, they will have the support of the tradition and, probably also, many available models to follow or flout.

Yet, while such verbalizing activities as storytelling, song-making, play-acting, reporting, and sermonizing may be found both throughout the world and throughout recorded history, literary genres do not cross linguistic and cultural boundaries totally unchanged. This disparity is one of the challenges of literary translation. Even when the chief countries of use have had long and close cultural connections, like England and France, the modes of writing and expectations of readers regarding genres may be slightly different. The differences are especially notable when cultural contacts are relatively recent and/or when language structures are acutely different, like English and Japanese. In such cases, accommodating genres may be even more challenging and transfer conventions more unstable. If to those issues is added the influence of cultural imperialism and postcolonial resistance, the translator's task may be more problematic still.

Let us look first at genres from sites of extended cultural contact. Countries with Western European cultures have developed transfer conventions, and this development means that readers of the first text (popularly called the 'original') read – or assume – the genre label and consequently expect certain features. French publishers, for example, will sometimes use the genre label as a veritable subtitle. They may do so even, perhaps especially, when the text is nontraditional. For example, with experimental fictions like Marguerite Duras, *Emily L. roman* ('Emily L. novel') or Samuel Beckett, *Comment c'est, roman* ('How It Is, novel') the genre subtitle probably elicits a certain kind of reading. Translators must take on the assumptions of the first-language readers and use the tools of literary analysis they have learned from their reading of both the source and target literary traditions. Translators usually operate intuitively at this stage of the project. That is, for example, if they already know they are dealing with a novel, they begin looking for tone, diction, hidden meanings, basic mythoi, etc.

At this point, translators must make a preliminary decision on how to use genre conventions. For example, in translating Baudelaire's *Les Fleurs du Mal*

(1857, 'Flowers of Evil'), which uses the hexameter, Stefan George had to condense when he decided to use iambic pentameter for *Die Blumen des Bösen* (1891). In this *tour de force*, he successfully approximated Baudelaire's rhyming also. The ultimate English translation of Baudelaire's *Fleurs* still seems elusive, although many talented poets have had partial success. Not only has condensation been a challenge, but rhyming, in and out of critical favor, has taken a toll on Baudelaire in English. With rhyme, there is the risk of forced semantic skewing or padded lines; without rhyme, there is often a refracted loss of melody.

Some subgenres are so specialized and so tied to the national tradition that gave rise to it that they are frequently referred to by the same word in a variety of languages. The Italian *novella* is such an instance, passing into English and German dictionaries as a relatively long fictional narrative, usually under 200 pages, frequently with a first-person narrator. The subgenre 'novelette' is presumably equivalent, but without such specific rhetorical features. The concept of genre, however, in these closely related cultures does not require great feats of imitation. Sometimes, the patronage system of the target culture will want a translation that fits seamlessly into the target literature, like John E. Wood's 1997 retranslation of Thomas Mann's encyclopedic *Doktor Faustus* (1947), in itself a compendium of a variety of medieval and modern German subgenres. (H. T. Lowe-Porter, in the first translation of 1948, had made a heroic effort in this respect also.) At other times, the patronage system decides to accommodate a boisterous genre that stands out from the norm like Gregory Rabassa's replication in Gabriel García Márquez's *Cien años de soledad* ('One hundred years of solitude,' 1967). Indeed, it is tempting to say that if Beckett's longer pieces of fiction had not been labeled 'novels,' readers might not have recognized them as such.

For examples of genre transfers between two markedly different languages and cultures, we can turn to the *haiku* and the *noh*. Here translators are really forced to adapt or simply incorporate an inspiration.

The haiku is an unrhymed Japanese poem where the three lines contain 5, 7, and 5 syllables; it has a close relationship to nature. The noh is a classic Japanese dance-drama with a plot relying on heroic narratives. The haiku has been successfully approximated by Western poets since the turn of the 20th century. It has become a recognized form of a very elliptical, imagistic poem with an elusive voice. The voice is elusive because it does not address the reader directly as in an epic poem; its voices are not played out in front of an audience as in a drama; and it is not overheard as in a lyric. A haiku's imagery is simply stated, thus making it a form that fills a niche in the Western prosodic repertory.

Western drama has not made room for the noh, even though it was chosen by Nobel Laureate W. B. Yeats as a poetic theater model for his own dramatization of heroes in Irish mythology. Possibly this lack of acceptance is because the noh is a **dance**-drama. The texts of noh plays represent only a fraction of the implicit play, which to be translated, really must be performed. Yet it remains a generic model for dramatists who want a highly stylized piece for audiences willing to take a play into their minds and forego watching action with which they can identify. As for any noh fad, there have been many dramatic subgenres that undermine the well-made play, codified by Aristotle and recurring throughout Western literature whenever a tight structure is in fashion, but it would be difficult to prove that the variations of Expressionism, Surrealism, Absurdism, etc., show more than coincidental similarities.

Tight structure, as would be found in French Neo-Classicists like Corneille, Racine, or Moliere or Naturalists like Ibsen, should be a reminder that great writers of genius can create a subgenre of their own. Shakespeare would be an example of a playwright with deceptively loose genres. Although he wrote comedies, tragedies, histories, and many permutations and combinations, if 'Shakespearean' is applied to another playwright's drama, the reader or spectator prepares for a play that overflows conventional expectations of plot, characterization, and scope, where the language does more than advance the momentum. It calls attention to itself by its transcendence of ordinary discourse. Critics are prompt to coin subgenres for the highly original rhetoricians; Calvino, Faulkner, Joyce, Kafka, and Proust immediately come to mind.

Indeed, as a word, genre is multipurpose and elastic. When Proust's Charles Swann exclaims in the last line of *Un Amour de Swann* ('Swann in love') that he wasted years of his life for a woman who wasn't even his *genre!* (his 'type'), he indicates not only the slippery semantic ground of this term, but also the unstable domain in which it is a convenient catch-all.

Translation and Genre: Sacred Texts

A Şerban, University of Montpellier III, Montpellier, France

© 2006 Elsevier Ltd. All rights reserved.

The translation of sacred texts is a particularly sensitive task. Sacred texts, or holy texts, have traditionally been considered to embody core values of particular cultures, guiding beliefs and behavior and influencing not only the lives of isolated individuals but also of large numbers of people, shaping the history of entire nations and continents, redrawing boundaries of states, and influencing cultural production in a number of interesting ways. Sacred texts such as the Bible and the Qur'an are considered by believers to be inspired by the Divinity; the Qur'an, for instance, is thought to contain, verbatim, the word of God revealed to the prophet Muhammad by the Angel Gabriel. This inevitably has important implications both for the legitimacy and acceptability of translations and for the methods of translation that should be used. More passionately than in the case of any other texts, the very right to exist is denied to translations of some sacred texts, and where translations are considered possible or even desirable, they are scrutinized with the greatest care by members of the hierarchical structure of the institution supporting each religion to ensure that no deliberate or nondeliberate distortion of the divine message has taken place. The first issue we need to address, then, is the very translatability of sacred texts and the legitimacy of translations.

The Translatability of Sacred Texts

Is the holy translatable? In order to answer this question, which has been at the center of theological debate for centuries, we would need to be able to define the holy – is it something that exists independent from our judgment of it, or is the aura of holiness the result of a consensus of a number of people who have adopted the view that a particular text is the word of God and hence is sacred? Then, we would need to establish whether the Divinity who is believed to have originated the sacred text encourages or forbids translation, and here we again find ourselves in the realm of theological controversy. Finally, we need to define translation, and this is a notoriously difficult task. All these questions may receive different answers depending on the religious tradition we subscribe to or the decision not to belong to any and, last but not least, on the theory of translation we adopt.

The biblical story of the tower of Babel has long fascinated translation scholars in the west (see Steiner, 1998; Derrida, 2002) and has been interpreted as a myth of the origin of translation, also giving rise to speculation about the relationship between translation and the holy. According to the Book of Genesis 11:1–9, all the people on earth originally spoke the same language. They decided to build a city with a great tower, so tall that its top should reach the heavens, but God confounded this activity by making them speak different languages. Because they could no longer understand each other, the people stopped building and scattered over the face of the earth. According to Derrida's reading, the fact that God destroyed both the tower and the original linguistic unity imposes and at the same time forbids translation. Translation is necessary if people are to be able to understand each other, and the translator's job is to remedy the scattering of tongues at Babel. But at the same time, by working toward the restoration of communication that God felt it necessary to destroy, the translator may in fact be working against God.

What is quite certain is that translation, including translation of sacred texts, does take place, even though many people do not always realize that the texts they are using have undergone at least one if not several translation processes. For example, the Jewish Torah, the equivalent of what Christians call the Old Testament, was translated from Hebrew into Greek in the third century B.C. (the famous *Septuagint*), from Greek into Latin (St. Jerome's influential *Vulgate*), and from Latin into a number of vernaculars. Buddhist texts were translated from Sanskrit and Pāli to Tibetan, Chinese, and Japanese and then into other Asian and European languages.

Given that translation attempts to restate a message in a new linguistic and cultural medium, it involves the recognition and at the same time the relativization of the importance and worth of each medium and the belief that the spirit and the letter are not inseparable. Christianity, for example, has embraced translation as a fundamental way of spreading its message across the world; according to Nida (1998: 23) at least one book of the Christian Scriptures has been translated into 2009 languages and dialects, spoken by at least 97% of the world's population. This Christian tradition of translation may be linked to the event of the Pentecost, when, filled with the Holy Spirit, the apostles addressed the crowd in a variety of languages, not just in Hebrew or Aramaic. Support for translation is also to be found in the New Testament in the letters of St. Paul. In the first letter to the Corinthians 14:13, St. Paul urged those who speak in an unknown tongue to pray that they may

also interpret. According to Toker (2005), the Pauline view is that the spirit, the Truth, is not tied to the sounds and words in which it finds its expression, but that it can be expressed in different words and in different tongues.

Other religions, however, resist translation, thus effectively claiming sacred status for the language in which they have their text. Thus, the *Megillath Ta'anith,* or *Scroll of Fasting* (also known as the *List of Festivals*), a first- or second-century A.D. writing, records the Judaic belief that three days of total darkness fell on the world when the Torah (or the Jewish Law) was translated from Hebrew into Greek. Furthermore, Steiner (1998: 63) shows that, according to the Talmud (a collection of Jewish oral tradition interpreting the Torah), the omission or the addition of one single letter of the Law might mean the destruction of the entire world. If we take this literally, the fact that translation involves altering completely the form or the letter of the text inevitably means that the Torah is untranslatable or, at the very least, that terrible consequences may be expected should anyone dare to undertake its translation.

Another sacred text that is considered by believers to be untranslatable is the Qur'an. To this day an influential school of thought subscribes to the view that any existing translations of it are illegitimate. One of the reasons cited in support of this opinion is the fact that, linguistically, the Qur'an is the masterpiece of the Arabic language and is considered to be of miraculous beauty; some scholars actually suggest that "the triumph of Islam was the triumph of a language, more particularly of a book" (Hitti, 1970: 91). Another argument in favor of the absolute untranslatability of the Qur'an is found in *aya* number 2 of the *sura* of Yusuf, which says that the holy book was sent down as an Arabic Qur'an. But even if the Qur'an were to be translated, how could a human translator cope with a text authored by God, a text whose very sounds originated in heaven? Because of all these reasons we find titles such as *The Meanings of the Glorious Qur'an* or *The Message of the Qur'an,* and not simply *The Qur'an,* as titles for translations. This implies not only a view of translations as inferior reproductions of an inimitable original, but also a view of translation as interpretation (see further below).

The belief in the superior, or even sacred, status of the language of a holy text is apparent even in religious traditions that do allow translation, such as Christianity. It has been the case that once the Bible was translated into a particular language, the translation itself was attributed a status virtually equal to that of the source text itself, and further retranslations were banned because they were believed to distort the word of God. Moreover, some of these translations acted as source texts for further translations into other languages; an example of this is St. Jerome's Latin *Vulgate*. In fact, in western Europe in the Middle Ages only three languages were considered suitable for religious expression: Hebrew, Greek, and Latin, and the liturgy in the Roman Catholic Church was performed in Latin. In the end a compromise was reached, and even though the Bible and the liturgy could only be read or recited in Latin, the use of vernacular for preaching was permitted. This compromise was taken a step further during the Reformation, when the Bible itself started being translated into vernaculars. As far as eastern Christianity is concerned, the Orthodox Church of Greece still uses the original text of St. John Chrysostomos' liturgy, which dates back to the fourth century A.D. and uses a language that is hardly accessible to speakers of Modern Greek. This situation is similar to that of the Old Church Slavonic text used by the Orthodox Churches of Russia, Serbia, and other Slavic countries; there is resistance to translating the liturgy into modern-day language, even though the Old Slavonic text is not an original but is in fact a translation from Greek. It appears that the form and content of a message are frequently perceived to be inseparable in the case of sensitive texts and that the power of tradition can be greater than the drive to adapt to contemporary linguistic realities.

Translating a sacred text must start from the premise that the same message *can* be conveyed in a different linguistic form, and this involves an optimistic view of translation or, perhaps, a deeply held conviction that even though imperfect, translation is necessary. But the fact that there are multiple translations into the same language of a sacred text such as the Bible suggests that there are more ways than one of approaching the task of translation; it also raises questions about which translated version is the correct one. Even though the differences between versions may seem relatively small to the uninitiated, some of them have caused huge doctrinal controversies. The institutions and people who accused translators of malicious distortion of the word of God and on a few occasions burned them at the stake acted in the name of their conviction that one translation was correct and another one wrong, but given the nature of the translational act, it is less than obvious how one can ever be so sure. According to Steiner (1998), translation, just as any other act of communication, involves interpretation, and more often than not, there are several possible interpretations. Although linguistic analysis and contextualization of the message can help eliminate some of these interpretations, it may still be necessary to choose

between those that remain. In a sense, then, by having to decide in favor of one of several possible alternatives, translation inevitably limits the meaning potential of a text, though at the same time it may open up a number of other associations. If, from a strictly linguistic point of view, there can be several translations or interpretations of a text, it is obvious that issues outside the text itself will be the ones to decide which interpretation is considered correct and/or acceptable.

The pressures on translators of holy texts are great, and they come from various quarters. Small wonder that this should be so, given that these translators work with texts "having a long history and involving the deep personal attachment of many people and the vast, vested interest of numerous institutions" (Nida, 1964: 26). Translators are not free to do what they like, because context and tradition tend to dictate the extent to which receivers will accept a particular translation as faithful, accurate, or effective (Nida, 1964: 179). To take this a step further, according to Shackle (2005) it is precisely context, rather than the content, of a text that makes the holy difficult to translate or even untranslatable; resistance to translation may actually be due to control of interpretation rather than to inherent textual untranslatability.

In 1529 Sir Thomas More, English humanist, writer, chancellor to King Henry VIII, and a devout Catholic, wrote his *Dialogue Concerning Heresies* and in 1532 the *Confutation of Tyndale's Answer.* Tyndale was the first person after the invention of printing to take steps toward translating and publishing the Bible in English; his vernacular translation was burned on the grounds that it promoted heretical ideas. Among the things that More objected to in Tyndale's translation are the renderings of a number of key words such as *senior* instead of *priest, congregation* for *Church,* and *love* for *charity.* According to More, Tyndale used *senior* or *elder* and not *priest* in order to promote the (Lutheran) view that priesthood is not a sacrament, as was believed in the Catholic church, but simply the office of a layperson appointed to preach. As for *congregation,* More's objection was that although the Church is indeed a congregation, not every congregation is the Church, and consequently people should not be misled into believing that all congregations are legitimate. Finally, according to More, charity always involves love, but love does not always involve charity. As explained in Long (2001: 143), in Latin there are two words for *love*: *amor* for physical, worldly love, and *caritas* for holy love, and even though in English the word *love* covers both meanings, *charity* was preferred because it was a closer derivative of *caritas* but also because it did away with any possible connotations of a physical type of love. In the Catholic Church, chastity was praised as a virtue and almost a prerequisite for holiness. Numerous other examples can be adduced to show how translational choices can give rise to doctrinal controversy. Perhaps one of the most famous examples is Martin Luther's German translation of the Bible, a crucial event in the history of western Christianity and a landmark of the Reformation. The particular way in which Luther rendered the verse in Romans 3:28, by adding the word *allein* (*only*), supported the doctrine of justification by faith alone (*sola fide*), which was different from the Catholic doctrine of salvation by faith and good deeds. To this day this is a major dogmatic difference between the Catholic Church and the Protestant Church.

To conclude, choices in translation, even when justifiable by linguistic analysis and by exegesis, can be extremely threatening to an established interpretation. And since translation is such a powerful means of challenging the accepted meanings of a holy text, it has been used time and again to bring about and justify change. Institutional control over interpretation is praised by some as a safeguard against error and is condemned by others as a restrictive, self-proclaimed monopoly on Truth. As explained in Long (2005: 3), the scattering of tongues at Babel obliges us to find a way of dealing with the multiplicity of interpretations either by fearing that they obscure God's message and lead us to chaos or by welcoming them as useful aids toward a multifaceted comprehension of the Divine. One can only hope that rather than producing confusion, the multiple translations of God's text(s) may actually be beneficial; after all, St. Augustine does say that "in fact, this diversity has helped rather than impeded understanding, if readers would only be discerning" (Gavigan, 1966: 74).

Main Issues and Strategies in Translating Sacred Texts

Not all religious texts have the same central status within a given tradition. For example, in addition to the holy book, the Qur'an, another source of authority underpinning Muslim life is to be found in the *hadith*, the sayings of the prophet Muhammad as remembered by those around him and written down after his death. The restrictions with respect to translation that apply to the Qur'an do not apply to the *hadith*; the *hadith* may be translated and quoted in translation because they are authored by a human and can therefore be translated by a human, whereas the Qur'an is believed to be authored by God.

In eastern Orthodox Christianity there are two major sources of authority: the Bible and the Tradition of the Church. The Tradition comprises a large body

of writings, some of which date back to the very beginnings of Christianity, oral teachings and customs, liturgical texts, stories about the lives of the saints, as well as core doctrine agreed on during the seven Ecumenical Councils that took place between the fourth and the seventh centuries A.D. The writings of the early church fathers such as St. Basil, St. John Chrysostomos or Golden Mouth, St. Athanasius and many others, have already been translated into a number of languages and so have collections of sayings from, and stories about, the lives of the fathers from the desert, founders of monasticism. In a sense, the Tradition is the very memory of the Church, a living repository that grows all the time because new experiences are constantly added to it, and translation is an ongoing activity. The status of some of these texts is difficult to overestimate: apart from guidance on doctrine, they offer detailed, practical advice on worship and everyday life. However, no single one of them is as important as the Bible, and this means less pressure on translators. Having said this, translation is not always an easy task because a good knowledge of the Bible and of the Tradition is usually required if one is to be able to translate these texts. And no translation is published without the approval of the hierarchy of the Church. Major undertakings such as retranslations of the Bible carry, on their first page, the approval of the Patriarch of the country; translations of other writings may also be published with the approval of a bishop.

The translation of a sacred text into a given language is influenced in a number of ways by previous translations of that or other texts belonging to the same religious tradition. If there has been previous translation activity, there might already be an established religious terminology and style. This can ease the translator's task considerably, but at the same time it may impose a number of restrictions in terms of what receivers are prepared to consider an acceptable translation. The reaction of the receivers is inevitably linked to their background, previous awareness of religious tradition, and the expectations they bring to their reading of the translated text (the issue of taking different audience groups into account when translating religious texts is discussed later).

It is interesting to notice that the holy text(s) of a culture may have marginal significance in another culture or may even be completely unknown, except perhaps to a number of converts, immigrants, or scholars. This is the case in Western Europe of the Orthodox liturgy of St. John Chrysostomos or of the Hindu holy book Baghavad-Gītā. Translating into a culture that already has its own religious tradition, and into a language whose religious vocabulary has developed in order to respond to the needs of the already existing religion, can be a challenging task. This is not least because the religious terminology that is required may either be unavailable, or, should translation equivalents exist, on closer scrutiny they are found to be loaded with semantic associations that are specific to the already established religion. For example, the English translators of the 1954 volume *Early Fathers from the Philokalia* (a collection of Christian patristic texts) discuss in their preface the example of the terms *theology* and *theologian*. They point out that in the Orthodox Church *theology* does not refer to systematic theoretical knowledge about God, which is the meaning generally accepted in Western Christianity. Rather, it refers to a gift of the Holy Spirit, the gift of speaking about God "with deep insight and with powerful and winning words" (Kadloubovsky and Palmer, 1954: 17). It is bestowed only on those who have attained wisdom and contemplation, and in the Orthodox Church the title of *theologos* is only given to three writers: St. John the Evangelist, St. Gregory of Naziansus, and St. Symeon the New Theologian.

In his discussion of cultural untranslatability of the Qur'an, Abdul-Raof (2005) explains that Arabic words such as *jannah* (paradise), *naar* (hell fire), or *haj* (pilgrimage), which appear to be easy to translate into English, relay different mental images and expectations than their English equivalents, which are rooted in the Christian religious tradition. The very word for God, *Allah*, evokes a number of associations that are specific to Islam, such as the ninety-nine attributes mentioned in the Qur'an, whereas the English word *God* is linked to the Christian dogma of the Holy Trinity (God as Father, Son, and Holy Spirit), a view that Islam does not share. Writing about a totally different religious tradition, Foiera (2005) notices that Buddhist texts translated into Italian, a culture and language heavily influenced by Christianity, are bound to be misunderstood because specific Buddhist concepts and practices are reconfigured by western audiences to correspond to preexisting Christian ideas such as the binary distinction between good and evil and the existence of an almighty God.

Because of the status of holy texts within given cultures and the importance attributed to the smallest textual detail, translation strategies have traditionally been source-text oriented, sometimes to the extent of attempting to achieve word-for-word equivalence. Even translators who advocate the merits of other translation strategies are cautious when it comes to translating a sacred text. Thus, in his 'Letter to Pammachius,' St. Jerome, translator of the Latin *Vulgate*, explains that a literal translation obscures

the meaning and admits that he prefers sense-for-sense translation to word-for-word translation, "*except in the case of the scriptures in which even the order of the words is a mystery*" (Lefevere, 1992: 47, my emphasis). Luther's German translation of the Bible was based on a more target-oriented approach to translating the holy text. As Luther himself explains in his 1530 'Open Letter on Translating,' his aim was to make the Bible accessible to common people by avoiding obscure expressions translated literally from another language and by using fluent German instead. However, Luther himself, as well as other translators of the Reformation era, did on occasion sacrifice this principle of intelligibility and reverted to literalism where essential theological aspects were concerned (Kirk, 2005: 90).

In the twentieth century, Bible translation took a significant step toward a view that translation should, above all, be communicative. According to this approach, which has become particularly influential not only in the area of Bible translation but also in the translation of texts other than the religious, the aim of translation is to communicate to a new audience, in a different language and cultural context, the same message that the author(s) of the source text intended to communicate to their original audience (see Nida, 1964; Nida and Taber, 1969; de Waard and Nida, 1986). In other words, translators should not aim for formal equivalence, but for dynamic (also known as functional) equivalence (i.e., equivalence of effect or response). For example, in John 6:24 "to give glory to God" actually means "to swear to tell the truth" (Nida, 1998: 24), and translators should opt for the rendering that makes it likelier that the average reader for whom a translation is intended will understand it correctly (Nida and Taber, 1969: 1). This method of translating involves a significant effort of interpretation on the part of the translator and presupposes that the translator is able to decide, based on scholarly evidence, what the correct meaning of the text really is. Communicative translation is inevitably based on a number of (warranted or unwarranted) assumptions about the response of the original audience as well as the likely response of those for whom the translation is intended.

Linked to the issue of formal versus dynamic equivalence as translation strategies is the issue of foreignization versus domestication in translation. A foreignizing approach involves moving the reader toward the original author, whereas a domesticating approach moves the author toward the reader. Domestication in particular has been criticized for attempting to turn a cultural 'other' into 'the same,' for reinforcing stereotypes, and in general for being an undemocratic form of cross-cultural communication (Venuti, 1995, 1998). According to Kirk (2005: 94), dynamic equivalence, as formulated by Nida, finds a valid middle way between the two strategies by rejecting domestication of the cultural background while encouraging linguistic domestication, though it is not always easy to make distinctions between the purely cultural and the purely linguistic aspects of a text.

The issue of style is very important when it comes to translating or retranslating a holy text, and one of the aspects usually discussed in relation to it is archaization versus modernization. Some people insist on having translations that sound ancient or even strange and unearthly because they feel these are more appropriate in view of the supernatural character of the message, whereas easy-to-understand renderings in modern idiom are considered to be less respectful of the text (Nida, 1997: 193–194). Also, there is a tendency in translation to use a higher register than the one in the source text; this is probably because of the perception that literary language fits the divine message better than a colloquial style. Those who disagree with this view consider that contemporary language is entirely appropriate as a means of conveying a spiritual message, and that believers should not prefer the emotional security of traditional religious style to the pursuit of a better understanding of the message itself (for a discussion of archaizing and modernizing strategies in English translations of the Orthodox liturgy of St. John Chrysostomos, see Şerban, 2005). Last but not least, no contemporary (re)translation of a sacred text can avoid taking one stand or another on the issue of gender-inclusive language.

Translation strategy will ultimately depend on a variety of textual and extratextual factors that include, but are not restricted to: reasons for (re)translating; aims to be achieved; the identity and background of the translator(s); assumptions about the targeted audience; pressures from tradition, commissioner, and audience; considerations of historical, social, and political background; and many other factors. Some translations are done to spread a message and others to refute it, such as, for instance, Robert of Chester's 1143 Latin translation of the Qur'an (Mustapha, 1998: 203). Other translations are done out of intellectual curiosity and the desire to make an exotic religion or way of life known to audiences at home; this has sometimes been a byproduct of colonialism and at the same time a means of reinforcing colonial relations. Some translators work on their own and others in teams; some are spiritual leaders in their respective tradition, and others are

scholars who have an academic interest in the religion whose texts they translate. At times retranslation work is motivated by the desire to improve the text as a result of contemporary scholarly advances in archaeology, textual criticism, or linguistics, whereas other retranslations aim to achieve a differentiated targeting of various audience groups.

It is now increasingly recognized that different audiences are best suited by different translation strategies; for example, editions prepared for teenagers, newly literate adults, or immigrants who are just learning the language of their new country may not be appropriate for highly educated audiences and the other way round. According to de Waard and Nida (1986), "all of these varieties of translating and adapting [e.g., formal equivalence, dynamic equivalence] have a certain legitimacy for particular audiences and special circumstances" (de Waard and Nida, 1986: 42, my addition). Thus, a more accessible level of language is called for if the translation targets children or the educationally disadvantaged, whereas a scholarly readership may prefer a more literal rendering accompanied by a critical apparatus in the form of preface, footnotes, dictionary of unusual words, index, and maps.

Needless to say, translators ideally have to work on reliable manuscripts, but even so, they may be confronted with errors. For example, in Mark 1:4 the Greek manuscript reads "as it says in Isaiah" but the words are actually from Malachi (Nida, 1998: 25). Kadloubovsky and Palmer (1954), the English translators of the *Philokalia*, reported being aware that some bibliographical details in the manuscript and some attributions of authorship (e.g., between the monk Evagrius and St. Nilus of Sinai) are questionable according to modern scholarship; however, they did not consider themselves to have the authority to make final pronouncements on these matters and decided to translate things as they are in the Russian version that they used as a source text.

When it comes to translations of holy texts, the question of *what* is translated can be just as important as that of *how* it is translated. Thus, Crosby (2005) argued that the nature of westerners' interest in Buddhism from the 19th century onward has had a major impact on the types of texts selected for translation into western languages; translations emphasize certain dimensions of Buddhism, such as the rational-scientific side, to the detriment of other aspects, such as ritual, daily practices, and ecclesiastical hierarchies. This has led to a view of Buddhism that is divorced from living Buddhism practiced by Buddhists.

Many important statements about translation have been developed as a result of work on sacred texts, and those that are best known in the west have come from translators and researchers of Christian texts, especially the Bible. This does not mean that statements on translation based on the experience of translating texts from other religious traditions and between languages other than western do not exist; it is just that scholarship is more compartmentalized than we would like to think it is, and access to the experience of other cultures is less than straightforward. Also, it is interesting to notice that not all cultures and religions place the same emphasis on written holy texts as the Judeo-Christian and Muslim traditions, and that for some religions oral modes of transmission may be just as important as writing.

It would be difficult to overestimate the impact that translating sacred texts has had, for better or for worse, on the world as we know it. Translators of holy texts have contributed to the spread of new ideas and ways of life; they have invented alphabets such as the Armenian and the Glagolitic and contributed to the rise of vernaculars and to the birth of national literatures. Directly or indirectly, their work has influenced numerous forms of cultural production besides literature, such as music, painting, and architecture (for a detailed overview of the role of translators through history, see Deslile and Woodsworth, 1995). The single most important factor in shaping 2000 years of European civilization and American civilization for the last few centuries has been the Judeo-Christian heritage; other religious traditions have had a similar impact in other parts of the world. On the negative side, in association with colonialism and other forms of unequal power relations, religious translation has worked toward the forceful imposition of new systems of values, sometimes to the extent of virtually wiping out preexisting civilizations.

In today's world, travel, access to the powerful new media, and intensified cross-cultural interaction linked to economic globalization have made it almost impossible to totally ignore the existence of other religions. This state of affairs creates interesting challenges for translators of holy texts and for translation scholars, who are suddenly faced with a different dynamics of cross-cultural communication than used to be the case in the not-too-distant past and with a different type of audience, who has access to a wealth of (sometimes conflicting) information. In addition to the old way of reaching audiences via printed books, religious messages can now be conveyed using the Internet and a variety of television programs such as feature films, cartoons, documentaries, televised sermons, and even advertisements. Consequently, the area of religious translation has recently broadened to include forms of multimedia adaptation

such as subtitling, dubbing, voice-over, and website translation, which will undoubtedly open rich avenues for interdisciplinary research.

While drama translation for the page has much in common with translation in other literary genres, transferring a play from one language into another for performance on stage presents the translator with problems of a different order. Unlike the reader of a play, a theatre audience is not in a position to consult footnotes or encyclopedias containing information about unfamiliar cultural concepts and social situations. With the exception of explanatory comments provided in performance programs, audiences are left

Translation Memories

U Reinke, Saarland University, Saarbrücken, Germany

© 2006 Elsevier Ltd. All rights reserved.

Translation memory (TM) systems, the most widely used toolkits in the localization of digital information, enable the translation and cultural adaptation of electronic content (e-content) for local markets. The idea behind TM systems is to store in a computer system the original e-content and the translation that has been produced by human translators; the stored translated version of the source document has been broken down into manageable units, generally one sentence long. Over time, enormous collections of sentences and their corresponding translations are built up in the systems. TM systems allow translators to recycle the stored translated segments by automatically proposing a relevant translation from the memory, either as a complete ('exact match') or as a partial ('fuzzy match') solution, whenever the same or similar sentences reoccur in the translation process. This increases a translator's productivity and helps ensure that terminology and expressions are consistently used across translations. Thus, TM systems facilitate and speed up the translation of an ever-increasing number of specialized texts.

Components of TM Systems

Apart from the 'memory,' or translation archive, as its core element, a typical TM system consists of an array of tools and functionalities to assist the human translator (see Figure 1). The system usually includes the following tools:

- A multilingual editor for reading source texts and writing translations in all relevant file formats of different word-processing programs, desktop publishing (DTP) systems, etc., protecting the layout tags of these formats against accidentally being deleted or overwritten.
- A terminology management program for maintaining termbases to store, retrieve, and update subject-, customer-, and project-specific terminology.
- An automatic term-recognition feature for automatically looking up in the termbase all terms that occur in the source text segment on which the translator is currently working.
- A concordance tool allowing users to retrieve all instances of a specific search string (single words, word groups, phrases, etc.) from a TM and to view these occurrences in their immediate context.
- A statistics feature providing a rough overview of the amount of text that can be reused from a TM for translating a new source document.
- An alignment tool to create TM databases from previously translated documents that are available only as separate source and target text files, by comparing a source text and its translation, matching the corresponding segments, and binding them together as units in a TM.

In addition, a few TM systems offer terminology extraction as an optional or an integrated feature to assist in populating termbases and in setting up the terminology for an e-content localization project by extracting mono- or bilingual lists of potential terms from a selection of electronic (source and/or target) texts. Increasingly, TM suites also include support for machine translation (MT), either by offering interfaces with MT systems or even by integrating their own MT component. Finally, some kind of project management (PM) support is built into most TM systems. These PM features may support the following functions:

- File handling and management (specification of all source language files, project-relevant termbases and TM databases, and assistance in defining folder structures).
- Management of client and translator data (addresses, contact persons, translators' skills, equipment, availability, etc.).
- Workflow management (deadlines, project progress, etc.).

The History of TM Systems

The basic idea of computer-assisted reuse of human translations can be traced back to the 1960s, when the European Coal and Steel Community (ECSC) developed and used a computer system to retrieve terms and their contexts from stored human translations by identifying those sentences with lexical items that most closely matched the lexical items of a sentence to be translated (Automatic Language Processing Advisory Committee, 1966: 27). A much broader reuse of existing machine-readable human translations with a clear focus on facilitating and accelerating revision processing, by identifying unchanged passages, was envisaged in a model developed by the translation service of the German Federal Army in the early 1970s (Krollmann, 1971). The notion of automatically retrieving 'exact matches' was first implemented in the early 1980s by ALPS, Inc. in a simple tool called 'repetitions processing,' as part of

Figure 1 Components and processes in a translation memory (TM) system (excluding project management and machine translation functionalities): ST, source text document; TT, target text document; TU, translation unit; TMX, Translation Memory eXchange format. Components and processes involved in the core translation process are shaded in light gray; optional preparatory components and processes are shaded in dark gray.

the company's commercial MT system. The reuse of similar sentences (fuzzy matching) was first suggested in the late 1970s in a paper by the European Economic Community (now called the European Union) translator Peter Arthern (1979), but commercial TM systems did not appear on the market until the early 1990s.

Types of TM Systems

In most systems available on the market, the TM is a database. Each record in a TM database contains a translation unit (TU) consisting of a pair of source and target text segments. In addition to the TU, there may be further information on the creation and modification dates, the person who created or modified the entry, the project(s) or customer(s) the TU is used for, etc.

Some TM systems do not make use of the database approach but store entire source and target text pairs in their proprietary formats as reference material for future reuse in related translation projects. While TM databases constitute an amalgamation of translation units that isolates each segment from its context, the reference text approach makes it easier to take context into account during the matching process. On the other hand, this approach is rather static, i.e., it is not possible immediately to reuse TUs that have just been created. Therefore, systems based on the reference text approach also create a so-called temporary fuzzy index, which is a kind of temporary database providing access to recently created TUs as well as fuzzy-match functionality.

Creation of a TM

Basically, there are three ways of feeding a TM: (1) while translating – when translating a text using a TM database, each segment from the source text will be automatically stored in the database along with its translation; (2) by importing another TM database – this can either be a TM created with the same TM system or with a TM available in the Translation Memory eXchange format (TMX), which is supported by all commercial systems; and (3) by aligning existing translations and their original texts – with the help of an alignment tool, it is possible to create TM databases from the source and target text files of previous translation projects.

TM Systems and Machine Translation

Translation memory technology is not to be confused with machine translation. Whereas MT systems translate without human intervention, TM systems provide features and tools to store and retrieve segments translated by a human translator. Despite this essential distinction between TM and MT, TM technology shares certain features with what is called 'example-based MT' (EBMT), an approach first suggested in Japan in the early 1980s (Nagao, 1984). Both TM and EBMT try to retrieve 'best matches' for the sentences of the text to be translated, from a bilingual text archive or database containing sentence-level alignments of existing translations and their original texts. Yet, there are fundamental differences between the purposes of EBMT and TM systems. A TM is mainly an information retrieval system that leaves decisions about whether and how to reuse and adjust the retrieved results – and thus the actual translation task – to the human translator. EBMT aims at producing translations by automatically selecting suitable fragments from the source language side of the retrieved TUs and building the translation from the corresponding elements of the target language side. Due to the complexity of this recombination task, not every TU contained in a translation archive is equally suited for reuse in TM systems and EBMT environments.

For good reason, MT has so far been used very little in high-quality e-content localization. MT is suited for only a very limited range of text types, and source texts have to be carefully tailored to the capabilities and restrictions of an MT system to minimize the amount of time and effort needed for postediting. Nevertheless, TM suites increasingly offer support for MT. Basically, there are two possible ways of combining MT and TM. The first way is batch processing (usually during project preparation). In a batch scenario, all segments of the source text that do not produce an exact match or a high percentage of fuzzy matches when being compared with the TM database may be exported for processing by MT. After the unknown segments have been translated by the MT application, the new translation units can be merged into the TM database. When the translator works on the text, the units generated by the MT system will be presented as candidate translations, possibly with a predefined matching penalty. The second way of combining MT and TM is interactive processing (during the proper translation stage). In an interactive scenario, translators can invoke the MT system each time there is no match with the TM database. If the result from the MT system proves helpful, it can be edited as necessary. The resulting translation unit will then be stored in the TM database for future reuse.

Figure 2 Examples in English (EN) and German (DE), demonstrating shortcomings of fuzzy match algorithms.

Advantages and Limitations of TM Usage

The advantages of using TM systems are fairly obvious: they increase the translator's productivity and enhance translation quality by ensuring that terminology and expressions are used consistently within and across translations. Users in industry and international organizations report a 25–60% rise in productivity. Yet, it must be stated that the use of TM systems may also have negative effects on translation quality. One of the major disadvantages of TM systems is that they usually operate at sentence level. Thus, there is a serious danger that the translator will focus too much on isolated sentences, possibly disregarding the contexts in which the sentences are embedded. Moreover, the matching algorithms of TM systems are based on very simple formal criteria, such as the similarity of character strings. Therefore, the human translator's notion of the degree of similarity between a segment to be translated and a segment retrieved from the database may differ considerably from the degree of similarity calculated by the TM system. This may lead to situations wherein exact matches yield wrong translations, or one translation of a fuzzy match requires little or no adjustment but another fuzzy match with the same similarity value is not useful at all (see Figure 2) (for a discussion on the aspects of evaluating the retrieval mechanisms of TM systems, see Expert Advisory Group on Language Engineering Standards (1996), Whyman and Somers (1999), and Reinke (2000a, 2004).

Despite the drawbacks, it should be noted that TM systems generally integrate into the translation workflow comparatively smoothly. As opposed to MT, they leave human translators in control of the actual translation process, while relieving them from routine work and maintaining translation as a creative act whenever the linguistic resourcefulness of a human being is required.

Translation of Scientific and Medical Texts

S L Montgomery, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

All types of knowledge, particularly in written form, are culturally mobile. They are capable of being transferred to new settings, absorbed by different peoples, even those of widely differing background and outlook. Translation is the linguistic process that makes this possible, whether for Homer's *Iliad* or Newton's *Principia Mathematica*. Translation is the act that renders knowledge, whether literary or scientific, a mobile form of culture. Such mobility, in turn, is what gives human understanding a deep and lasting influence beyond the borders of its original setting.

Discussions related to the theory, practice, and history of translation have tended to focus on literary and holy texts. Yet translation has been a central determinant in the history of scientific knowledge as well, therefore a crucial element in its intellectual history, and continues to be so today. Indeed, modern science and medicine would be inconceivable without the contributing elements of Greek, Hindu, and early Islamic thought, which came to Europe through several major episodes of translation. Today, moreover, the works of Newton, who wrote in Latin, Pasteur (French), and Einstein (German) are found in every major language of the world, and important scientific and medical papers, books, reports, procedures, and much more are made available to all nations through the effort of translators.

Despite such importance, science and medical translation has been a topic of only sporadic scholarly study. The so-called 'invisibility' of the literary translator, whose labor and worth tend to be ignored in favor of the original author, doubly applies to the scientific translator, who has been neglected

Translation of Scientific and Medical Texts

S L Montgomery, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

All types of knowledge, particularly in written form, are culturally mobile. They are capable of being transferred to new settings, absorbed by different peoples, even those of widely differing background and outlook. Translation is the linguistic process that makes this possible, whether for Homer's *Iliad* or Newton's *Principia Mathematica*. Translation is the act that renders knowledge, whether literary or scientific, a mobile form of culture. Such mobility, in turn, is what gives human understanding a deep and lasting influence beyond the borders of its original setting.

Discussions related to the theory, practice, and history of translation have tended to focus on literary and holy texts. Yet translation has been a central determinant in the history of scientific knowledge as well, therefore a crucial element in its intellectual history, and continues to be so today. Indeed, modern science and medicine would be inconceivable without the contributing elements of Greek, Hindu, and early Islamic thought, which came to Europe through several major episodes of translation. Today, moreover, the works of Newton, who wrote in Latin, Pasteur (French), and Einstein (German) are found in every major language of the world, and important scientific and medical papers, books, reports, procedures, and much more are made available to all nations through the effort of translators.

Despite such importance, science and medical translation has been a topic of only sporadic scholarly study. The so-called 'invisibility' of the literary translator, whose labor and worth tend to be ignored in favor of the original author, doubly applies to the scientific translator, who has been neglected

even by the field of translation studies, with a few important exceptions. These exceptions – for example, concerning the transmission of ancient Greek and medieval Islamic science – reveal an interesting truth: no less than with literary works, translators of science and medicine have often imposed new elements upon the texts they have rendered, enriching and expanding them by adaptation to new cultural contexts. Just as the world has benefited greatly from the translation of scientific and medical knowledge into many languages, so has this knowledge been advanced by translation in turn.

The Translation of Scientific Works: Assumptions and Realities

There are several widely held assumptions about the linguistic transfer of scientific texts. One holds that science translation is literal, mechanical work, since it deals only with informational content embodied in terms that have exact equivalents in every language. Thus, a complete one-to-one correspondence exists: word-for-word translation is not only possible, but necessary. Such assumptions grow from the fundamental idea that scientific language constitutes a universal form of human discourse. It follows from this that any transfer among languages merely involves the production of duplicates.

These ideas are disproved by several realities. First, linguistic universality implies a fixed and final, ahistorical discourse. Yet, scientific speech has changed profoundly over time, even during the past century, not only in vocabulary, but in grammar and in many rhetorical elements (techniques of persuasion). Prior to the late 19th century, the written style of physics, astronomy, chemistry, and medicine shared many ingredients with literary and philosophical expression, common to educated discourse as a whole. Galileo's *Sidereus nuncios* or Darwin's *Origin of Species* were composed according to the general standards for elegance of their era (late Renaissance Latin, Victorian prose). Thus, translation of scientific literature can involve many of the identical challenges claimed for works in the humanities.

Close analysis also reveals that the subsequent evolution of technical discourse toward a more instrumental style has not occurred uniformly across languages, but instead has been quite variable. It is instructive to consider an example, from a published abstract in geology:

> En effet, quel que soit le site initial des séries les plus compétentes, celles-ci ont finalement tendance à occuper une position structurale haute en fin de déformation (Turki *et al.*, 1988: 399).
>
> [Published version in English] Therefore, despite the initial configuration, the most competent strata will reach the highest structural position at the end of deformation.

The more literary character of the French compared with the English version is clear. Results of professional translation today, like the above, indicate that one-to-one correspondence in scientific translation does not exist. A more accurate rendering of the original French (Therefore, whatever the initial setting of the most competent strata, these have a tendency, finally, to occupy a high structural position at the end of deformation.) would not likely be considered proper scientific style in English. In addition, the experience of machine translation has shown that word-for-word renditions utterly fail to yield a publishable result and are often, in whole or part, incomprehensible.

Comparative linguistics, meanwhile, argues that languages inevitably evolve out of specific cultural circumstances and are never pure replicas of one another. This applies to professional discourses, too, which are more than terminology alone. At base, a physics paper in German cannot be perfectly copied into Chinese or Russian for the same fundamental reasons that this cannot be done for novels: differences in grammar, syntax, usage, etc. Interpretation is always involved in translation, and this includes scientific material. The scope of such interpretation has changed over time, for several reasons. One reason relates to the evolving character of scientific discourse itself, which, as noted, was quite diverse for most of its history.

Another central factor is the wide range of standards – or lack thereof – used in translation generally during premodern times. The common idea that translators have always chosen between a 'literal' and a 'free' approach – an idea, it should be said, that comes from the writings of translators themselves – is far too simplistic to describe what actually occurred. Certainly, translators were often free to do as they saw fit, there being no official rules for correctness and seldom any means of accountability. This freedom allowed for relatively literal equivalents, to be sure, but also for a wide range of methods, both written and oral, by individuals, partners, even groups. In ancient and medieval translations, it is typical to find that original material has been deleted, added to, edited, reorganized, and very often, when the source was difficult to understand, unintentionally corrupted. In some cases, for example Ptolemy's *Syntaxis Mathematica*, the text was divided up into chapters and sections, figures were changed or added, and even a new title given (*Almagest*). As a result, individual texts tended to

undergo a degree of cultural-linguistic adaptation, or nativization, to each new setting. This could affect the more technical content peripherally or in a more substantive fashion. Either way, during the great majority of history, translators understood their work as involving the creation of new originals.

Role of Translation in the History of Science

No original scientific, medical, or mathematical text from classical antiquity has survived to the present. The oldest versions date from around the 8th century and afterward; thus, for authors such as Euclid, Archimedes, Galen, and Aristotle, more than 600 years removed. What exists, therefore, are copies of copies, and, in many cases, copies of translations of translations (for Galen's medical works, Latin versions of Arabic translations of Greek and Syriac copies). This is also true for many works of Islamic, Hindu, and Chinese science, particularly before the era of print. The importance for the history of science is considerable. Prior to the advent of modern experimental work and the rise of the technical journal in the 17th and 18th centuries, this history was largely a tale of books and their influence. Major periods of advancement often came as a result of expanding the written foundations of science, mainly through the incorporation of new texts from outside.

Modern science had its most immediate beginnings in Europe, mainly in the later 16th and the 17th centuries. However, the intellectual seeds from which 'natural philosophy' grew were planted much earlier, in the late medieval period, when the greater part of a massive body of scientific knowledge and philosophy was decanted into Latin. This material had a number of cultural and historical sources: Late Classical and Hellenistic Greek thought; Nestorian scholarship of the Near East; Hindu mathematics and astronomy; Islamic science of 9th–12th centuries. The material brought into Europe, mainly from Arabic and, to a lesser extent, Greek, combined ingredients from all these sources and proved enormously rich, nutritive. It was at this time that the basic texts of mathematical astronomy (Ptolemy, al-Tusi), geometry (Euclid), algebra (al-Kwarizmi), optics (al-Hazen), mechanics (Archimedes), medicine (Ibn Sina, Galen), and a dozen other fields, as well as Arabic numerals, the sine function, and the zero (all of Hindu origin) entered Europe. Men such as Adelard of Bath, Gerard of Cremona, and William of Moerbeke gained no small fame at the time for the many translations they produced.

Their effort, however, was possible because it drew directly upon the fruits of a similar episode several centuries older. In fact, it was the great Arabic translators – Hunayn ibn Ishaq above all, but many others, such as Thabit ibn Qurra – who had collected and rendered scientific texts from all parts of the Near East and beyond, and who drew on works in Syriac, Greek, Pahlavi, and Sanskrit for this purpose. The great flowering of intellectual life in early Islam, by which the Near East arguably became the most advanced, enlightened region on Earth, was deeply dependent upon the incorporation of this diverse knowledge through translation.

In more recent times, translation has been the basis for the initiation of a modern scientific culture in non-Western nations. In Japan, for example, nearly all early scientists (late 18th and early 19th century) were translators first: their work involved increasing the number of scientific texts for study, adapting these works to Japanese uses, and attempting to further the knowledge gained thereby. This could mean certain adaptations, reflective of the cultural-historical moment, such as the rendering of the 'survival of the fittest' concept as 'victory of the superior over the inferior' in a late 19th century, militarizing Japan. Ironic consequences could also occur, for instance related to the refusal or inability to translate important works. Jesuit missionaries of the 17th century, notably Matteo Ricci, introduced western astronomy to China, yet, due to dictates of the Counter-Reformation, were forbidden to profess the heliocentric system. Thus, when the Chinese eventually encountered this system later on, in the translated works of Galileo, Kepler, and Newton, they rejected it in favor of a pre-Copernican universe.

In today's world, translators of scientific and medical material are commonly employed by governments, universities, research institutes, corporations, foundations, journals, and other important institutions throughout the world. The influence of such translators on the present development of science is therefore no less profound, historically speaking, than in the past.

Cultural Importance

It follows from the above that the translation of scientific and medical works has been an important element in the modernization of societies. Technical know-how, rendered into native languages, has provided different cultures with potent intellectual ingredients for material advancement. This is a broad statement and suggests many questions about the exact role translation has played with regard to the introduction of modern mathematics, theoretical and applied, medicine and medical technology, military techniques and technology, and scientific research in general.

On the linguistic side, it is clear that science and medical translators have greatly expanded all the major languages of the world. In former centuries, these translators have often been involved in the creation of new vocabularies. On the other hand, it is estimated that scientific terms comprise well over half of all English words – this language now being the dominant world discourse for science and medicine – suggesting that the same is true or will soon be true for other tongues as well. While it is true that most scientific and medical literature is published in English today, researchers still employ their native languages to communicate among themselves and to perform experimental work. As a result, the writing of publishable articles in English involves an effort of translation, one with distinct cultural dimensions. The future of science, practically and culturally, therefore appears deeply bound up with the phenomenon of translation.

In sum, the task of the scientific translator, no less than his or her literary relative, has been to create new texts, to multiply sources into new languages, thereby to produce new originals that can be studied, taught, absorbed, and that therefore become fertile cultural material. Over time, translation has made of science a great library, ever more enriched, accessible, and expanding.

The Classical Period

Jewish Translation

Translation was a constant of ancient civilizations – there are bilingual inscriptions from Assyria and Mesopotamia (3000 B.C.) and the Rosetta stone from Egypt (196 B.C.). Most of these translations dealt with administrative and commercial matters. The Jewish translators of the Old Testament were based in Alexandria, then one of the most important Greek-speaking cities in the Mediterranean. By 200 B.C. they were facing a dilemma. On the one hand, most Jews living outside Palestine could not understand Hebrew well enough to read the Scriptures. On the other, translation of the Scriptures was tampering with the Word of God. Both Jewish theology and Neoplatonist philosophy agreed that the Divine Word illuminated the human soul and mind and that names directly reflected natures. One could avoid negating the creative power of the Scriptures only by strict word-for-word translation. The Greek version of the Hebrew Scriptures, the Septuagint, was complete by about 150 B.C. The persistent legend that the 70 translators were left in solitary confinement each with a Hebrew text and in 70 days each produced identical texts shows that literal translation was accorded mystical value.

Roman Translation

In ancient Rome, translation was always done from Greek texts, normally as a rhetorical or creative task. Roman thought on the craft was summed up by the 1st-century rhetorician Quintilian, who repeated the ideas of Cicero and Horace, seeing translation as 'rivalry' of the original author. The one dissenting voice was the philosopher Seneca the Younger, who demanded that if truth was to be kept, translation should be strictly literal.

In about 250 B.C., Livius Andrónicus, a Greek slave captured at Tarentum in southern Italy in 272 B.C. produced a Latin version of the *Odyssey* that was still being used as a textbook in Roman schools a couple of centuries later. In the meantime, soldiers and other administrators were coming back to Rome with a taste for Greek amusements, particularly theater. Enterprising writers supplied the need by free translation and even adaptation from Greek dramatists. The two most famous of these Roman dramatists of the generation after Livius Andronicus, Plautus (d. 184 B.C.) and Terence (190–159 B.C.), were regarded as authorities on translation until the end of the western Roman Empire.

The greatest age of Roman literary translation lasted from the 1st century B.C. to the middle of the 1st century A.D. The Roman Golden Age set the custom, which lasted until well into the 20th century, of treating translation as a literary apprenticeship and constant exercise. Most of the extant poets had some translation in their corpus; for example, Cicero's major contribution was to create scientific terminology through his versions of Greek philosophy. Translation remained common in the centuries following, one notable translator being the philosopher Apuleius (120–155), the author of *The golden ass*.

The importance of literary translation has obscured the immense amount of Roman technical and scientific translation. There was a small corpus of medical translators whose adherence to the originals by Hippocrates, Galen, and some minor Greek medical writers was typical of technical work in all ages. Drawing on the talent at his disposal, the Emperor Augustus set up a translation office as part of the imperial household to assist in administering the Empire. Its most prominent piece of work is the *Monumentum*

Conclusion

Looking back at attitudes in the 1970s and 1980s, translators were insular and considered any criticism (albeit constructive) as an affront to their competence as a translator. The concept of planned continuing personal development had not been considered. Technology has changed almost beyond recognition, as has the way in which most translators work. Although I am heartened by the way in which the profession is developing, translators need to realize their true worth and promote themselves as professionals if they are to receive just rewards for their labors.

Translation Units

K Malmkjær, Middlesex University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The Unit of the Translation Product

The definition and identification of the unit of translation depends on whether the translation product or the translation process is being considered. When the translation product is at issue, translation units are pairs of source and target text segments (*see* **Translation Memories**); these segments can be identified as source and translation by mapping the units of the target text onto the units of the source text (Toury, 1986). Studies that have compared translation and source text pairs produced by novice translators with pairs produced by experienced translators show that the units formed in novice-translator pairs are smaller in extent and generally are of a lower linguistic rank (word, phrase) than are those (clause, sentence) formed in pairs produced by experienced translators.

The Unit of the Translating Process

When the process of translating is at issue, the translation unit is understood to be that stretch of the source text that the translator keeps in mind at any one time, in order to produce translation equivalents in the text he or she is creating (Lörscher, 1991). These units can be identified during 'talk aloud protocol' studies (TAPs) (*see* **Think-Aloud Protocols**), and, like the product-oriented studies, TAPs suggest that whereas learner translators tend to view a word or a phrase as the unit of translation, more experienced translators focus on larger stretches of text as translation units. Note in this connection that some research suggests that the verbalization process of TAP studies has a shortening effect on translation units.

Translation Units and Translation Equivalents

Translation units (however understood) cannot be identified with translation equivalents, for two reasons. First, the former regularly determine the latter; second, whereas translation equivalents, being formal, may be fairly fixed for some expressions, translation units, in the cognitive sense of units of attention, tend to vary according to the translator's personal past history and general mental capacities. Consider the potential text segments 'six' and 'feet' cooccurring in the uninterrupted sequence, *six feet*. The translation equivalent for the two-word sequence will tend to vary depending on the cotext in the sentence; in this case, the choices may be between the body-part sense of 'feet' and the unit of measurement. Thus, before an equivalent can be selected, it is necessary to consider at least the stretch of cotext that explains which sense is meant, and that stretch will then be the translation unit. Potential units in the example here might be 'all of its six feet' in a sentence such as *The monster put socks on all of its six feet*, and 'six feet tall' in *Jack is six feet tall*. If the unit initially identified as instrumental in determining where equivalence is to be established and what it is to be were in fact 'six feet tall,' then, as far as a translator *in medias res* is concerned, it may be necessary to break this unit down into two smaller units, namely, 'feet' and 'six,' so that a measurement

equivalent of feet (say, centimeters) could be multiplied by six to arrive at the correct metrical expression of the height. However, the translator may have come across this height indication often enough before to remember the metrical equivalent, in which case 'six feet' will not need to be broken down into subunits.

Translation Universals

A Mauranen, University of Tampere, Tampere, Finland

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The search for translation universals began in the early 1990s, with roots in translation studies and corpus linguistics. In translation studies, the fundamental influence came from descriptive translation studies, which shifted the focus in translation research from the relationship between source and target texts to translations themselves.

The second major impetus came from outside translation studies: the extension of large electronic corpora to translations provided a chance of seeing large-scale patterning in translated language. Earlier, contrastive linguistics had begun to employ corpus data based on translations, but its priority lay in comparing the source and target languages.

It was Mona Baker's seminal paper in 1993 which brought together the traditions of descriptive translation studies and corpus linguistics (Baker, 1993). She suggested that this combination made it possible to investigate those linguistic features which typically occur in translations rather than nontranslated texts, and which are not dependent on the specific language pairs involved. Baker defined translation universals as

> ... universal features of translation, that is features which typically occur in translated texts rather than original utterances and which are not the result of interference from specific linguistic systems. (Baker, 1993: 243)

Baker saw in electronic corpora a useful testing ground for hypotheses concerning universals that had been put forward by other scholars, mainly on the basis of small-scale studies. The assumptions or hypotheses included features such as a tendency towards explicitation, disambiguation, and simplification, growing grammatical conventionality and a tendency to overrepresent typical features of the target language, as well as the tendency to reduce or remove repetitions. Following the publication of Baker's article, the idea of linguistic translation universals has found a place at the center of discussion in translation studies, and empirical studies have begun to proliferate.

Corpus data is so different from the kind of evidence that scholars in language-related disciplines were traditionally used to that it has surprised linguists, lexicographers, and translation scholars. The number of instances it yields of repeated items and patterns transcends our intuition about language. Different kinds of corpora have been used to study translations, but the terminology concerning corpus types is somewhat unstable. Nevertheless, three types can be distinguished: a 'parallel corpus' consists of texts and their translations; a 'comparable corpus' consists of matched subcorpora compiled on similar principles in one language, with one subcorpus of translations, and the other of comparable texts written originally in the same language; a 'bilingual corpus' is an umbrella term for any corpora involving two languages.

For patterns and distributions in translated language, we are still in the early stages of discovery. Although more recent findings have thrown light on early hypotheses, they also reveal a more complex picture of the phenomena and processes involved. Also, some hypotheses seem to concern the relationship of sources and their translations, while others have been concerned with translated and nontranslated texts, but these have not always been kept apart. Many hypotheses have process-related names, like 'simplification' and 'explicitation' even if they do not

equivalent of feet (say, centimeters) could be multiplied by six to arrive at the correct metrical expression of the height. However, the translator may have come across this height indication often enough before to remember the metrical equivalent, in which case 'six feet' will not need to be broken down into subunits.

Translation Universals

A Mauranen, University of Tampere, Tampere, Finland

Introduction

The search for translation universals began in the early 1990s, with roots in translation studies and corpus linguistics. In translation studies, the fundamental influence came from descriptive translation studies, which shifted the focus in translation research from the relationship between source and target texts to translations themselves.

The second major impetus came from outside translation studies: the extension of large electronic corpora to translations provided a chance of seeing large-scale patterning in translated language. Earlier, contrastive linguistics had begun to employ corpus data based on translations, but its priority lay in comparing the source and target languages.

It was Mona Baker's seminal paper in 1993 which brought together the traditions of descriptive translation studies and corpus linguistics (Baker, 1993). She suggested that this combination made it possible to investigate those linguistic features which typically occur in translations rather than nontranslated texts, and which are not dependent on the specific language pairs involved. Baker defined translation universals as

> ... universal features of translation, that is features which typically occur in translated texts rather than original utterances and which are not the result of interference from specific linguistic systems. (Baker, 1993: 243)

Baker saw in electronic corpora a useful testing ground for hypotheses concerning universals that had been put forward by other scholars, mainly on the basis of small-scale studies. The assumptions or hypotheses included features such as a tendency towards explicitation, disambiguation, and simplification, growing grammatical conventionality and a tendency to overrepresent typical features of the target language, as well as the tendency to reduce or remove repetitions. Following the publication of Baker's article, the idea of linguistic translation universals has found a place at the center of discussion in translation studies, and empirical studies have begun to proliferate.

Corpus data is so different from the kind of evidence that scholars in language-related disciplines were traditionally used to that it has surprised linguists, lexicographers, and translation scholars. The number of instances it yields of repeated items and patterns transcends our intuition about language. Different kinds of corpora have been used to study translations, but the terminology concerning corpus types is somewhat unstable. Nevertheless, three types can be distinguished: a 'parallel corpus' consists of texts and their translations; a 'comparable corpus' consists of matched subcorpora compiled on similar principles in one language, with one subcorpus of translations, and the other of comparable texts written originally in the same language; a 'bilingual corpus' is an umbrella term for any corpora involving two languages.

For patterns and distributions in translated language, we are still in the early stages of discovery. Although more recent findings have thrown light on early hypotheses, they also reveal a more complex picture of the phenomena and processes involved. Also, some hypotheses seem to concern the relationship of sources and their translations, while others have been concerned with translated and nontranslated texts, but these have not always been kept apart. Many hypotheses have process-related names, like 'simplification' and 'explicitation' even if they do not

refer to differences between source texts and their translations.

The idea that translation studies ought to search for general laws and regularities is not new. Gideon Toury proposed this as a fundamental task of descriptive translation studies at the beginning of the 1980s (and again in 1995). Similar suggestions have been made since: for example, Andrew Chesterman envisaged translation studies as a rigorously scientific pursuit, seeking generalizations like any other science.

Theoretical modeling of the nature of translated language has included conceptualizations of translation as constituting a language form of its own, which is not reducible to either the source or the target. Notions of this kind have been put forward in terms of translations as 'hybrid language,' or as a 'third code.' Although some suggestions about laws of translation imply a broader view of universals than linguistic – cognitive processes for example – the main focus of the research has so far been on linguistic features.

The Concept of Translation Universals

Since the idea of universals was introduced, many scholars in translation studies have hastened to dispute the validity of the concept, while agreeing that it is nevertheless very interesting. As one consequence, alternative terms and concepts have abounded; 'laws' and 'tendencies' have appeared more acceptable to many than 'universals.' The disputes reflect different understandings of the term 'universal,' but there seems to be more conceptual than terminological unity in the field.

One of the most influential scholars advocating the search for general laws of translation is Toury, who avoids the term 'universals.' He proposes (1995) some general laws ("the law of growing standardization," "the law of interference"), which have subsequently been taken up by other scholars for further empirical validation. Recently he has characterized such laws as probabilistic propositions or conditioned regularities. In his view, the chief value of such laws lies in their explanatory power.

On similar lines, Chesterman argues that the quest for generalities which characterizes all science should also be one of the prime tasks of translation studies. Seeing universals as one route to high-level generalizations, he distinguishes (2004) two types of universals: one relates to the process from the source to the target text (what he called 'S-universals'), the other, 'T-universals,' compares translations to other target language texts. Chesterman's distinction clarifies discussion, but empirical research does not seem to divide the field up equally clearly. The S-type has been studied less with large databases than the T-type, although it can fruitfully be investigated with parallel corpora.

One of the strongest objections to the search for universal laws has come from translation history: for instance Tymoczko (1998) maintains that the very idea of making claims about universals in translation is inconceivable since we have no way of capturing translations from all times and all languages. This can be countered by observing that we need not have access to all translations that have ever existed to be able to posit general laws – for any field of research, access to data is limited, but pursuing generalities is based on the data we have. Nevertheless, the status of translations relative to spontaneous texts in a given language can have changed radically: translations have often preceded domestic texts, provided models for new genres, and generated linguistic innovations, and the borderlines between translations, adaptations, and texts otherwise heavily influenced by foreign sources tend to remain indeterminate.

Considerations of this kind impose limitations on the claims made about translation universals, but fuzzy categories and boundaries are typical rather than exceptional for many objects of study in the humanities and social sciences. In any case, translation studies rest on the idea that translations exist, and are sufficiently identifiable to warrant research.

In linguistics, universals have been investigated and debated for many decades. It has become generally accepted that a fruitful study of language universals needs to take into account different kinds of general tendencies insofar as they are shared by a large number of languages, not only 'absolute' universals. As Greenberg *et al.* put it in their classic 'Memorandum concerning language universals': "Language universals are by their very nature summary statements about characteristics or tendencies shared by all human speakers." (Greenberg *et al.*, 1966: xv) A similar extended view, which includes tendencies, seems also appropriate to translation studies. Moreover, the distinction in linguistics between universals which can be traced back to general human cognitive capacities and those which relate linguistic structures and the functional uses of languages appear equally relevant to translation universals.

The term 'universals' does not, then, necessarily refer only to absolute laws which are true without exceptions. Rather, most of the suggested universal features are general or law-like tendencies, or high probabilities of occurrence. Because the empirical study of translation universals is relatively new, the hypotheses have tended to be very general, even

vague, of the type 'all translations are X,' or 'all translations have a tendency to Y.' Few more specific hypotheses have been presented yet, but the empirical work so far seems to suggest that the reality of translations is likely to be more complex, and have more determinants than the first generation of hypotheses would suggest.

Hypotheses Concerning Translation Universals

Hypotheses on universals presented by various translation scholars at different times and in different places were first gathered by Baker. These hypotheses were often based on small-scale studies of language pairs. They overlap in part, and some have established themselves better than others. Below, the three most firmly established hypotheses are briefly presented and discussed, followed by three more recent ones. It must be kept in mind that the first hypotheses originated in possibly incomparable circumstances and on the basis of small and specific data; before large-scale empirical data was available, it was difficult to focus predictions precisely.

The most established and extensively studied hypotheses are 'explicitation,' 'simplification,' and 'conventionalization.' Three newer hypotheses have grown out of large-scale observations in corpus research in the early 2000s: 'underrepresentation of unique target language items,' 'source language interference,' and 'untypical collocations.'

Explicitation

The most widely accepted hypothesis, which tends to receive support but relatively little counterevidence is one which predicts that translations are more explicit than source texts, in other words that the translation process tends to add information and linguistic material. Explicitation has mostly been studied as an S-universal, but increasingly also as a T-universal.

Blum-Kulka (1986) noticed that translations contained more redundancy and explicit cohesion than their source texts, and called this tendency 'explicitation.' Since then, a number of studies have found support for explicitation at different levels of language. Baker (1996) observed that translations tend to contain more explanatory lexis (such as *cause, due to, lead to*) and connectors, more syntactic repetition, and more textual extensions such as parentheses, dashes, footnotes, and paraphrases of metaphors. Olohan and Baker (2000) observed a related tendency to use rather than omit an optional relative pronoun in reporting clauses (*he said that it's all right* rather than *he said it's all right*). Johansson (1998) noticed that translations between English and Norwegian (Norwegian, Bokmaal) in either direction were longer in terms of number of words than their originals. Culture-specific phenomena also tend to be replaced by better-known hyperonyms (*shilling – coin*), or explanatory paraphrases. Some findings suggest genre-related differences: the finding that the number of connectors in academic texts increases in translation has not been confirmed for the genre of children's literature. Occasional findings seem to speak against increased explicitness: Puurtinen (1995) found more nonfinite clauses in translated children's literature than in nontranslated literary texts for children. However, this was not confirmed by Eskola (2002), who discovered that clause type and source language influenced the choices of finite vs. nonfinite structures.

Explicitation has thus been observed in different aspects of language – syntax, lexis, and text, as well as culture-specific concepts, but there seem to be more constraints in operation than merely the fact that a text has been translated – the level of language investigated, the genre of the text, as well as temporal or cultural distance between source and target are likely to affect the level and kind of explicitness in translations.

Simplification

In contrast to explicitation, the hypothesis of simplification has given rise to much controversy and conflicting results. One problem is the definition of simplification, which has turned out to be difficult to agree on. Inherent problems are involved in that simplification at one level may lead to increased complexity at another. So, for example, simplifying sentence structures by converting sentences to simple main clauses with few subordinate clauses may lead to greater complexity at text level, reducing its coherent flow, and making it seem fragmented and hard to follow. Similar conflicting processes have been found in second language users, who appear to compensate for their simplification of target language morphology by employing periphrastic syntactic means instead. Moreover, simplification has been postulated for both S- and T-type hypotheses, which may have caused some of the confusion, since scholars have meant different things by it, perhaps not always being aware of this.

As a process term, 'simplification' is more appropriate in referring to shifts from the source to the target text than to differences between translated and nontranslated texts, but it has also been applied to the latter setting. Some suggested simplifications, such as the tendency to shorten sentences, seem to depend on individual translators' preferences, and not to qualify as universal.

The characteristics interpreted as manifestations of simplification have included above all lexical simplification, which Laviosa-Braithwaite (1996) found in her influential research on lexis in translated language. Laviosa-Braithwaite's study was the first large-scale investigation with the explicit objective of testing hypotheses about translation universals. Her corpus was of the comparable type, comprising original English newspaper texts and corresponding translations from several source languages. Her findings indicated that translations had a lower type-token ratio, a lower lexical density, and a proportional overrepresentation of the most frequent lexis. Yet lexical simplification has not always been confirmed: for example Jantunen (2001) found no support for it. Methodological differences may play a role, since Laviosa-Braithwaite compared overall word frequencies, whereas Jantunen looked into a selection of individual items in greater detail. Detailed analyses tend to show that the behavior of different items is not identical, and therefore other factors need to be considered in addition to an overall tendency. The increased complexity of the hypotheses needed for the next stage of universals research is also apparent from investigations of syntax and connectors: particular structures or items manifest patterning which may be interpreted as increased simplicity; others do not.

Conventionalization

Another common observation concerning translations is their general tendency towards conventionality, sometimes called 'normalization.' This tendency relates to a general conservatism said to characterize translations – a tendency to avoid the margins, to remain within established mainstream usage. Conventionalization has been viewed both as an S- and a T-type hypothesis, which, as pointed out above, may lead scholars to talk at cross-purposes. Conventionalization was conceptualized earlier by Gideon Toury, who talked about "the law of growing standardization." (Toury, 1995) By this Toury meant what he termed the tendency of translations to replace textemes with repertoremes (1995: 268), that is, the tendency of translations to modify the textual relations in the source text in favor of more habitual options in the target language linguistic repertoire. The conventionalization hypothesis bears some affinity to the simplification hypothesis: both quote the great lexical frequencies of frequent items as evidence in support of their claims.

Empirical work has reported that translations favor unmarked grammar, clichés, and typical, common lexis instead of the unusual or the unique; replace standard language for dialect; and normalize punctuation and exaggerate target language features. A further source of evidence has been found in the greater proportions of n-grams, or recurrent multiword clusters, in translational data as compared to spontaneous texts. Kenny's (1996) corpus-based study on conventionalization focused on 'hapax legomena' (i.e., words which only occur once in a given database), finding evidence to support the hypothesis, but on account of the considerable variation among individual translators (and even in one translator's strategies in different contexts), she concluded that the tendency to avoid hapaxes in translations more than in originals is not likely to be a universal.

Opposite tendencies have also been reported: Toury referred generally to "the well-documented fact that in translations, linguistic forms and structures often occur which are rarely, or perhaps even never encountered in utterances originally composed in the target language" (1995: 208). Mauranen reported untypical collocations in translations, and Jantunen found translations to have greater variety among the collocates of frequent intensifiers. Altogether, the tendency of translations to favor conventional, middle-of-the-road language has not been demonstrated, and anecdotal evidence of linguistic oddity in translations is common.

Underrepresentation of Unique Target Language Elements

Tirkkonen-Condit (2004) puts forward a hypothesis that linguistic features which tend to be unique to the target language, or in any case do not occur in the source language, are proportionally underrepresented in translations. Such unique features are also sometimes referred to as 'untranslatables.' This directly contradicts the earlier hypothesis that features specific to the target language get overrepresented in translations.

Tirkkonen-Condit's research on Finnish (Standard Finnish) clitics and verbs of sufficiency strongly supports her hypothesis, showing that these elements occurs more rarely in translations. Her suggested explanation is that these items are missing from a translator's bilingual 'mental dictionary,' because they have no counterpart in the source language, which would make up the other half of the entry, as it were. Therefore, they have a slighter chance to be chosen for the target text than they would have if the text was written directly in the target language. Tirkkonen-Condit thus presents this as a T-universal. Nevertheless, her explanation reaches out towards the cognitive domain, bringing in a process angle on the observations that originated in studying the linguistic product.

Supporting evidence for the hypothesis has also come from the realm of syntax, where Eskola (2002) noticed that certain target-language nonfinite constructions were underrepresented in translations when the source language did not possess a directly corresponding structure. Further lexicogrammatical support has also come from the rare use of the Finnish 'zero person' in translations, although it is highly characteristic of Finnish spontaneous usage. This evidence comes from both comparable and parallel corpora (Mauranen and Tiittula, 2005).

Support for this hypothesis has hitherto been strong, but although the studies have involved more than one source language, they have mostly had Finnish as the target language. An earlier study by Gellerstam (1996) on Swedish was nevertheless in accordance with it: a few Swedish discourse particles were underrepresented in translations from English, where they had no direct counterpart. In all, the hypothesis seems promising, but requires further research in a wider variety of target languages.

Source Language Interference

At first sight, it would seem that there is nothing new in the hypothesis that the source language causes interference in translations. This appears to be the first commonsense explanation that comes to mind when people uninitiated in translation studies seek an explanation for translational oddities. However, interference has been problematic in the study of universals, since Baker's (1993) initial definition seems to exclude interference completely. The idea that interference is a general law of translation was nevertheless included in Toury's (1995) "law of interference," and later other scholars postulated this as a possible universal, for example, Laviosa-Braithwaite (1996), Eskola (2002), and Mauranen (2004).

Eskola's (2002) research on nonfinite constructions compares translations from Russian and English and discovers that Finnish translations tends to overrepresent those structures which have a straightforward counterpart in the source language. The interference hypothesis has also been supported in lexical studies. Both Jantunen (2004b) and Mauranen (2004) use subcorpora with 10 source languages as well as subcorpora with a single source language. Single-source translations differ from those representing a variety of source languages. While differences in translations from individual source languages seem to support the interference hypothesis, translations on the whole are closer to each other than to target language originals. This seems to indicate that although interference exerts a strong influence, it does not entirely explain the specificity of translations.

Corpus-based studies supporting the universal of interference have used a research design for T-universals. Yet their conclusions invoke the source language, which suggests that while the distinction between S- and T-universals adds to conceptual clarity, it gets blurred in actual translations.

Untypical Collocations

This hypothesis, suggested by Mauranen (2000), relates to earlier findings indicating that distributions of language items in translations are different from their distributions in spontaneous text in the same language. These observations are of the T-type, all based on large comparable corpora.

Laviosa-Braithwaite (1996) investigated individual word forms and found that the most frequent words were proportionally overrepresented in translations. The untypical frequencies Gellerstam (1996) found comparing translated and original Swedish concerned different kinds of linguistic items; for example, nominal headwords were more frequent in translations into Swedish than in original Swedish texts, whereas Swedish attitudinal particles were less frequent; certain reporting verbs were differently distributed. Mauranen (2000) studied item combinations, both 'collocations' (the tendency of words to co-occur more frequently than could be expected by chance) and 'colligations' (the habitual combination of a lexical item with a grammatical category). According to her results, translations favor combinations which are possible in the target language system, but rare or absent from actual texts. Conversely, translations often have few or no instances of combinations that are frequent in target language texts. These findings do not necessarily contradict those indicating that frequent items are even more frequent in translations; individual items in the combinations may be frequent, even if their co-occurrence is unusual.

This hypothesis is in accordance with Kenny's (1999) results on collocational differences in hapaxes, and has found some, although not unequivocal support in Jantunen's (2001) investigation of near-synonymous intensifiers and their combinatory tendencies: he found both under- and overrepresentation of collocations, colligations, and cluster sequences of several words in translations. Variation was item-specific.

Colligations straddle lexis and grammar. Jantunen's study was concerned with highly frequent intensifiers, which can be regarded as partly grammaticalized and be placed on a continuum between grammar and lexis. Another combinatorial observation is that fixed word sequences are more common in translations. Altogether, combinations deserve more

attention since they may resolve some contradictory findings.

Approaches to the Study of Translation Universals

The chief value of research on universals lies in deepening our understanding of translation, and contributing to translation theory. No single research method can be regarded as the sole or best means of approaching universal properties of translations. In the discussion hitherto, three broad strands can be discerned: linguistic, cognitive, and social. The first two relate to the well-established categories of translation product and translation process. The third draws on sociocultural research, which has often been hostile to general laws, but may conceivably contribute to interesting generalizations.

The Linguistic Approach

Most research into translation universals has been linguistically oriented. The systematic research on translation universals originated in corpus studies, although developments in translation theory constituted important prerequisites.

Corpus methods are well suited for the discovery of large-scale linguistic tendencies, and they can therefore reasonably be expected to continue to play a major role in universals research. Corpora have benefited research on parallel texts by providing a much larger number of examples that can be retrieved simultaneously for scrutiny than was possible earlier. Large numbers help us get away from individual translators' idiosyncrasies, and enable an overview of what is typical as well as the extent of variation and the detection of the unique.

A more radical departure from tradition has been the development of comparable translation corpora. By excluding access to source texts, they force scholars to focus their attention on the target text and the target language. These databases have also enabled comparisons between translations from different sources and one target language. Similarities between translations from different sources, which set them apart from target language originals, provide good candidates for several universals; conversely, features typical only of a single source language are likely to be caused by interference. It is important to include a variety of source languages in comparable corpora, so as to distinguish that which is shared by all translations, and equally important to compare findings in different target languages to exclude that which is language-pair specific.

The Cognitive Approach

The cognitive approach (see, e.g., Jääskeläinen, 1999; Alves (ed.), 2003) has remained largely at the level of theoretical discussion, but it has also featured in empirical research as a model for explaining the characteristics of translated texts. The translator's cognitive processes are seen as the mediating element which accounts for the shifts that are linguistically manifest. This seems a major direction where explanation is sought for large-scale observations in corpus-based studies. While some scholars make explicit reference to cognitive concepts like the translator's bilingual mental dictionary, others have remained at more commonsense levels of process description, talking about translators' tendencies to translate word for word, or to translate that which is stimulated by the source text. Statements of the latter kind point to a need for modeling linguistic findings about translation also in process terms.

The Social Approach

The social approach has mainly taken a critical stance in relation to translation universals (see, Tymoczko, 1998; Paloposki, 2002). Sociohistorical views tend to emphasize the particular over the general, and this research has problematized simple notions of translation. Historical examples show that source texts may have undergone such major transformations that any attempt at direct linguistic comparison is ruled out, and cases where it may be difficult to identify a source language, let alone a source text, are known even in the contemporary world, for example in the E.U. Translations have played a major role in bringing new genres and text types into cultures, which implies that domestic counterparts to translations cannot always be found even in well-established national writing cultures. Basically, the comparative study of translations with either their sources or matching texts written in the target language assumes a distinguishable source and its translated counterpart, which in certain respects is a simplification.

Social constraints may weaken the comparability of texts even if source texts and their translations are identifiable without problems: translations are not distributed evenly across the genres of the target culture, nor is their social status homogeneous. An important factor is what Toury (1995) called "preliminary norms," that is, the translation policies which determine things like the selection of texts for translation. For a given language pair, more tends to get translated in one direction than the other. In addition, translations in one direction are likely to be differently biased for social determinants like prestige, or date of original. The ensuing dilemma is that

the comparability of texts conflicts with the objective of reflecting prevailing preliminary norms, although an ambitious corpus would wish to incorporate both criteria.

These facts limit any unproblematic comparability and remind us of likely sources of systematic bias in large databases. However, while the constraints must be kept in mind, they do not invalidate the search for generality, since ideally homogeneous databases can hardly be compiled with real language and real translations. A search for generality cannot assume homogeneity of the research object; rather, it consists in search for the shared within the variation.

Conclusion

The quest for universals is by its nature international and collaborative. It is vital to combine findings from a wide variety of languages and language pairs, both typologically distant and close.

It is also necessary to involve all levels of language. Both lexis and grammar have been investigated, with their overlapping areas to an extent, but textual phenomena have been comparatively neglected. Moreover, both process and product need to be covered, which implies taking on board a variety of research methods. Even though corpora provide a unique opportunity to observe large-scale phenomena, establishing universals of cognitive processes requires psycholinguistic means. The implications of sociocultural research are also important in informing linguistic and cognitive studies of the wider contexts that shape translations.

So far most empirical investigation into translation universals has focused on linguistic characteristics, while theoretical discussion has concerned the plausibility, kinds, and possible determinants of universal tendencies. The field is still young, and it is to be expected that the evidence which is accumulating from empirical studies will open many new questions.

Translational Equivalence

S L Halverson, University of Bergen, Bergen, Norway

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The concept of equivalence can be identified as one of the most contentious, and thus potentially most significant, concepts in the study of translation. Debates have centered on how the concept is to be interpreted, the domain of its application, and the extent to which it is even useful in the study of translation.

In understanding the controversy, it is helpful to keep in mind the basic components of the concept of equivalence. 'Equivalence' is defined as the state of being 'equivalent,' which, in turn, is defined in the *Collins English dictionary* (1986: 516) as being, among other things:

1. equal or interchangeable in value, quantity, significance, etc., or
2. having the same or similar effect or meaning.

As suggested by these two main entries, the concept includes three key elements: two entities between which a relationship holds, a relationship (of equality, interchangeability, sameness, similarity), and a quality or feature according to which the relationship between the two elements is defined (e.g., value, quantity, significance, effect, meaning, etc.). As we shall see, various elements of this notion will be more or less in focus in the evolving debates. However, there has been no disagreement on the basic content of the notion.

The following presentation includes a brief historical overview of the development of the equivalence concept in translation studies. Next, two complementary views of this historical development are presented. In the final section, the *status quo* will be briefly sketched.

A Brief Historical Overview

Chesterman (1998: 16–27) provides an insightful chronology of the debate on equivalence in translation studies. In his account, Chesterman describes three distinct stages in the historical development. These three stages coincide in large part with the key stages discussed in Pym (1995) and Halverson (1997). In the following, Chesterman's outline will serve as the starting point, and the contributions of the latter two will be addressed in the section on the development in context.

The Classical Period

Jewish Translation

Translation was a constant of ancient civilizations – there are bilingual inscriptions from Assyria and Mesopotamia (3000 B.C.) and the Rosetta stone from Egypt (196 B.C.). Most of these translations dealt with administrative and commercial matters. The Jewish translators of the Old Testament were based in Alexandria, then one of the most important Greek-speaking cities in the Mediterranean. By 200 B.C. they were facing a dilemma. On the one hand, most Jews living outside Palestine could not understand Hebrew well enough to read the Scriptures. On the other, translation of the Scriptures was tampering with the Word of God. Both Jewish theology and Neoplatonist philosophy agreed that the Divine Word illuminated the human soul and mind and that names directly reflected natures. One could avoid negating the creative power of the Scriptures only by strict word-for-word translation. The Greek version of the Hebrew Scriptures, the Septuagint, was complete by about 150 B.C. The persistent legend that the 70 translators were left in solitary confinement each with a Hebrew text and in 70 days each produced identical texts shows that literal translation was accorded mystical value.

Roman Translation

In ancient Rome, translation was always done from Greek texts, normally as a rhetorical or creative task. Roman thought on the craft was summed up by the 1st-century rhetorician Quintilian, who repeated the ideas of Cicero and Horace, seeing translation as 'rivalry' of the original author. The one dissenting voice was the philosopher Seneca the Younger, who demanded that if truth was to be kept, translation should be strictly literal.

In about 250 B.C., Livius Andrónicus, a Greek slave captured at Tarentum in southern Italy in 272 B.C. produced a Latin version of the *Odyssey* that was still being used as a textbook in Roman schools a couple of centuries later. In the meantime, soldiers and other administrators were coming back to Rome with a taste for Greek amusements, particularly theater. Enterprising writers supplied the need by free translation and even adaptation from Greek dramatists. The two most famous of these Roman dramatists of the generation after Livius Andronicus, Plautus (d. 184 B.C.) and Terence (190–159 B.C.), were regarded as authorities on translation until the end of the western Roman Empire.

The greatest age of Roman literary translation lasted from the 1st century B.C. to the middle of the 1st century A.D. The Roman Golden Age set the custom, which lasted until well into the 20th century, of treating translation as a literary apprenticeship and constant exercise. Most of the extant poets had some translation in their corpus; for example, Cicero's major contribution was to create scientific terminology through his versions of Greek philosophy. Translation remained common in the centuries following, one notable translator being the philosopher Apuleius (120–155), the author of *The golden ass*.

The importance of literary translation has obscured the immense amount of Roman technical and scientific translation. There was a small corpus of medical translators whose adherence to the originals by Hippocrates, Galen, and some minor Greek medical writers was typical of technical work in all ages. Drawing on the talent at his disposal, the Emperor Augustus set up a translation office as part of the imperial household to assist in administering the Empire. Its most prominent piece of work is the *Monumentum*

ancyranum, Emperor Augustus's own statement of his achievements, translated as a blatant piece of propaganda. This translation office remained active until after the fall of Rome in the 5th century.

Christian Translation

Christian translation, from Greek into Latin (except for Ulfila's 4th-century Gothic version of the Bible) began in the 2nd century A.D. with the *Shepherd of Hermas* and parts of the Bible. The Jewish Platonist ideas on the relationship between language and the divine flourished in their assiduously literal style. Translation of Greek Christian liturgies for Latin speakers began soon after. The Christian tradition culminated in the work of St Jerome (348–420), famous for his Latin version of the Bible, the Vulgate (383–406) and for a huge number of miscellaneous translations covering Church administration, monastic rules, and theology. However, he was only one of a very skilled band of translators that included his former friend Rufinus (345–410), the philosopher Marius Mercator (ca. 400–450), and a large number of anonymous churchmen.

Roman translation came to an end with Boethius (480–524). He had meant to stave off the tide of barbarism attendant on the collapse of the Roman Empire by producing Latin versions of the complete corpus of Plato and Aristotle but was executed for treason in 524 with only a small part of the work done. His versions revert, to the stricted type of translation thought proper by Biblical translators. His preface to Porphyry's *Isagoge*, which castigates elegance as inimical to 'truth,' may owe as much to Seneca as to the Judeo–Christian tradition.

The Middle Ages

Translation from Greek to Latin

Although Jerome was revered and quoted right through the Middle Ages and the Renaissance as the main model for translation, the medieval tone was set by Boethius. His methods were followed by Cassiodorus (ca. 490–583). Between 550 and 560, Cassiodorus assembled a stable of translators in a monastery in Calabria, called the Vivarium, dedicated to preserving classical culture. He, like Boethius, had the ambition to translate the whole of Greek philosophy and theology into Latin. Though he did not succeed in this aim, he put translation on a sound administrative footing that kept cultural lines open with the Greek East. From the 6th until the 16th centuries there was a flourishing traffic of religious translations between East and West.
